Supplemental Draft Environmental Impact Statement/
Final Environmental Impact Report

EOEA #10458

Logan Airside Improvements Planning Project

Boston Logan International Airport

Massachusetts Port Authority

Federal Aviation Administration

March 2001

Volume 1

Preface

The Boston Logan International Airport Airside Improvements Planning Project Supplemental Draft Environmental Impact Statement/Final Environmental Impact Report (Supplemental DEIS/FEIR) is jointly prepared by the Federal Aviation Administration (FAA) and the Massachusetts Port Authority (Massport). The FAA is the lead federal agency for purposes of Airport Layout Plan (ALP) approval and any federal funding approval, which are federal actions subject to the National Environmental Policy Act (NEPA). The FAA is also the project proponent with respect to the reduction in runway approach minimums for Runways 15R, 22L, 27 and 33L, and implementation of runway instrumentation. Massport is the project proponent for all of the other identified improvement concepts comprising the Preferred Alternative, which fall within its purview as proprietor of Boston-Logan International Airport.

This Supplemental Draft EIS has been prepared in response to a decision by the FAA, and to satisfy the procedural requirements of NEPA; the Council on Environmental Quality's (CEQ) *Regulations for Implementing the Procedural Requirements of the National Environmental Policy Act of 1969,* as amended, 40 CFR Part 1500; and the FAA's Airport Environmental Handbook (FAA Order 5050.4A). This document has also been prepared to satisfy the requirements of the Massachusetts Environmental Policy Act (MEPA) and its implementing regulations.[1] Because the document fulfills both federal and state purposes, it is referred to as a Supplemental Draft Environmental Impact Statement/Final Environmental Impact Report.

Federal EIS Process

On February 1, 1999, Massport, in a joint effort with the FAA, submitted a Draft Environmental Impact Statement/Environmental Impact Report (Airside Project Draft EIS/EIR) for the Airside Improvements Planning Project (Airside Project). Approximately 500 comment letters were received during the applicable Airside Project Draft EIS/EIR federal and state comment periods from various governmental entities, including the US Environmental Protection Agency (EPA), the Massachusetts Department of Environmental Protection, the Massachusetts Natural Heritage and Endangered Species Program, the City of Boston, various elected and other public officials, community groups, individual residents and other interested parties.

1 301 CMR 11.00 MEPA Regulations

In January 2000, following issuance of the Draft EIS, the FAA called for preparation of a Supplemental Draft EIS to address specific issues identified by the FAA as a result of comments received during the DEIS review process. At the FAA's direction, a Supplemental Draft EIS Panel (SDEIS Panel), consisting of three members appointed by the Governor of the Commonwealth of Massachusetts and three appointed by the Mayor of the City of Boston, was formed. Under the direction of the FAA New England Region, the SDEIS Panel convened in March of 2000 and then met 12 times, concluding with a final meeting in December of 2000. In addition to these formal meetings, the SDEIS Panel also made visits to Hanscom Field, Worcester Regional Airport, T.F. Green / Providence Airport, Manchester Airport, and the Logan ATC Tower. To provide the the SDEIS Panel with appropriate background, it was presented with: (a) an Interim Supplemental Draft EIS to the Airside Project Draft EIS / EIR; (b) answers to key letters written by members of the public, concerned agencies and public officials responding to the Airside Project Draft EIS / EIR; and (c) a series of 15 visual and written presentations from the Airside Project's technical consulting team and other independent transportation industry experts, both in favor of and in opposition to the Airside Project (minutes from the SDEIS Panel meetings are contained in Appendix A). This document reflects a special set of work tasks developed by the FAA as a result of the SDEIS Panel review process and constitutes the Supplemental Draft Environmental Impact Statement.

State EIR Process

The Draft EIR was the subject of an extended pubic comment period including public hearings on April 7, 1999 at the State Transportation Building in Boston and April 8, 1999 at the Holiday Inn in East Boston. On May 7, 1999 the Massachusetts Secretary of Environmental Affairs issued a Certificate ("EOEA Certificate") on the Draft Environmental Impact Report (Draft EIR) for the Logan Airside Improvements Planning Project. The Secretary determined in his Certificate that the Draft EIR had adequately and properly complied with the Massachusetts Environmental Policy Act (MEPA) (M.G.L. c. 30, ss. 61-62H) and its implementing regulations (301 C.M.R. 11.00). The Secretary also found that the Draft EIR presented enough information on alternatives, impacts and mitigation to meet the MEPA standard and should therefore proceed to the stage of a Final EIR. The EOEA Secretary directed that the Final EIR must address certain specific issues, as well as adequately respond to the substantive comments received. This document responds to the EOEA Certificate and includes separate volumes containing responses to comments received on the Airside Project Draft EIR.

Organization of this Supplemental Draft EIS/Final EIR

The Airside Project Draft EIS / EIR, submitted in February 1999, provided a comprehensive assessment of the benefits and potential impacts of all the project alternatives in accordance with federal and state scoping directives. Potential impacts were identified by category and quantified in relation to the proposed alternatives. This Supplemental DEIS / FEIR is

intended to complement and to be reviewed in conjunction with the Airside Project Draft EIS/EIR. As explained below, each chapter in this Supplemental DEIS/FEIR summarizes the major findings of the Airside Project Draft EIS/EIR, focuses on additional analyses conducted for the Supplemental DEIS/FEIR, and documents impacts associated with the Preferred Alternative. The "Key Points" section at the beginning of each chapter summarizes the key points for that chapter from the Airside Project Draft EIS/EIR, and reflects analyses conducted in response to the EOEA Secretary and/or the FAA's work tasks for the SDEIS.

A comparison between the chapters of the Airside Project Draft EIS/EIR and this Supplemental DEIS/FEIR is provided in Table P-1 at the end of this Preface. Table P-2, also at the end of this Preface, outlines the analysis tasks required by the FAA as a result of the SDEIS Panel process. To assist the reader, the table outlines where these analyses are located within the Supplemental DEIS/FEIR.

The document is comprised of an Executive Summary and 11 volumes, the contents of which are summarized below.

Executive Summary	Available as a separate volume
Volume 1	Preface Executive Summary, Chapter 1 - Project Background, Purpose and Need Chapter 2 - Logan's Role in the Regional Transportation System Chapter 3 – Alternatives Chapter 4 - Delay Analysis
Volume 2	Chapter 5 - Affected Environment Chapter 6 - Environmental Consequences Chapter 7 - Cumulative Impacts Chapter 8 - Preferred Alternative and Mitigation List of Preparers Reviewers List Acronyms Index
Volume 3 Appendices	Appendix A - FAA SDEIS Panel Process Appendix B - Regional Transportation Appendix C - Delay Appendix D - Northwest Wind Runway Use Restriction Appendix E - Noise Appendix F - Air Quality Appendix G - Wildlife Appendix H - Cultural Resources Appendix I - Environmental Justice Appendix J - Construction
Volumes 4 – 11 Responses to Comments	EOEA Certificate and Responses Comment Letters and Responses

- **Preface** – Provides a guide to the organization of this Supplemental DEIS/FEIR and its relationship to the Airside Project Draft EIS/EIR.

- **Executive Summary** – Provides an overview of the Supplemental DEIS/FEIR and is published as a separate document.

- **Chapter 1: Project Background, Purpose and Need** – In the Airside Project Draft EIS/EIR, this chapter served as an introduction and provided the foundation for the project purpose and need. In this Supplemental DEIS/FEIR, this chapter presents a summary of the key points in the Airside Project Draft EIS/EIR and provides further clarification of the delay problem at Logan Airport. In response to a number of substantive comments, including those of the FAA, the SDEIS Panel and the EOEA Secretary, this chapter provides historical context for Logan Airport's delay problem; compares Logan Airport to other major U.S. airports; provides a more comprehensive discussion of delays; and guides the reader through complex delay terminology and the different measures of delay. Chapter 1 broadens the discussion of delays to include those that are caused by Logan Airport, as well as those incurred by Logan Airport passengers but caused by conditions at other airports or Air traffic Control (ATC) related problems. To respond to a FAA SDEIS work task, Massport has also attempted to assess the effect that Runway 14/32 would have had on Logan Airport's national delay ranking in 1998 if it had been available.

- **Chapter 2: Logan's Role in the Regional Transportation System** – In the Airside Project Draft EIS/EIR, Chapter 2 evaluated the extent to which regional transportation options, including other New England airports and advances in passenger rail services, may affect projected passenger demand at Logan Airport. Many comments received on the Airside Project Draft EIS/EIR focused on regional transportation issues and the importance of planning in a regional context. In response to the high level of public interest and concern regarding this topic, the EOEA Secretary instructed Massport to significantly expand upon the regional transportation analysis that was presented in the Airside Project Draft EIS/EIR. The FAA SDEIS Panel reinforced the Secretary's concerns. Throughout the 10-month panel review process, the SDEIS Panel indicated the need for ongoing regional planning by all relevant regional transportation agencies. As a result of these concerns, and as a follow-up to an earlier planning effort, Massport, the FAA, the regional airports, and New England state aviation planning agencies are conducting a new regional aviation system planning initiative, the New England Airports System Study.

  Chapter 2 describes the purpose and proposed scope of work for the New England Airports System Study, which will be sponsored by the FAA, the regional airports and Massport. Chapter 2 also provides an updated and more detailed analysis of regional transportation options, including a discussion of the evolving roles of the major commercial airports that will serve a majority of the region's passengers for the foreseeable future, namely Boston-Logan International Airport; T.F. Green Airport in Warwick, Rhode Island; Manchester Airport in New Hampshire, and the Worcester Regional Airport in Massachusetts. New analysis is presented to quantify the

potential role to be played by Worcester in providing relief for Logan Airport in the western portion of its service area and what Massport and the other state transportation agencies are doing to encourage that function. In addition, in response to the directive of the EOEA Secretary, Massport reports on the current status of proposed ground access improvements at Logan, Manchester, T.F. Green / Providence and Worcester airports and quantifies any effects these changes would have on passenger demand at these airports. In view of the recent rapid growth enjoyed by the regional airports and their impact on diverting traffic from Logan Airport, the forecast period has been extended from 2010 to 2015, when Logan Airport is expected to serve 37.5 million air passengers. The analysis supporting this extended forecast period is described in Chapter 2.

- **Chapter 3: Alternatives**– In the Airside Project Draft EIS / EIR, Chapter 3 provided a detailed description of the Alternatives analyzed as part of the Airside Project as specified in federal and state scoping directives. In this Supplemental DEIS / FEIR, these alternatives are reviewed again, but in more summary form. In response to FAA's additional work tasks for the Supplemental DEIS, this chapter further clarifies the proposed Centerfield Taxiway and the number of aircraft queuing on that and other taxiways. In response to a number of comments on the Airside Project Draft EIS / EIR, this chapter also includes a more detailed discussion of Massport's Program for Airfield Capacity Efficiency (PACE), which provides a more complete context for previous demand management programs at Logan Airport, and examines the PACE impact for relevance to the Peak Period Pricing concept currently under consideration. Chapter 3 also discusses demand management strategies already in place at other US and international airports.

- **Chapter 4: Delay Analysis** – In the Airside Project Draft EIS / EIR, Chapter 4 discussed the passenger and aircraft operations forecasts, the delay modeling methodology and the results of the airfield delay analysis. Both the EOEA Secretary and the FAA asked for clarification regarding the use of 1993 as a base year. Chapter 4 of this Supplemental DEIS / FEIR incorporates 1998 operational data to supplement and update the 1993 analysis. By applying the same capacity and delay modeling completed for the 1993 Historic Modeled condition, as well as the future forecast scenarios, the addition of the 1998 Actual Condition provides a current assessment of delay levels at Logan Airport.

  Chapter 4 includes updated operational and environmental analyses of 1998 conditions similar to that contained in the *Logan International Airport 1998 Annual Update (October 1999)*. While the *Logan International Airport 1999 Environmental Status and Planning Report (ESPR) (December 2000)* includes updated analyses for 1999, the differences between the two study years are small. Since the relevant comparison for evaluating the proposed Airside Project improvements is the comparison between the No Action and Preferred Alternatives, and since 1998 and 1999 are similar in terms of passengers, operations, and environmental impacts, this Supplemental DEIS / FEIR includes the 1998 modeling analysis as a representation of recent conditions at Logan Airport.

The FAA conducted further analysis to better understand the future role of regional jets (RJs), which are rapidly being added to airline fleets at Logan Airport. Specifically, the FAA suggested examining the delay reduction effectiveness of the proposed 5,000 foot runway given a fleet with more regional jets than previously forecast. This Supplemental DEIS/FEIR presents a third fleet for the 37.5 million air passenger level (37.5M) that reflects a high proportion of regional jets, and a correspondingly low proportion of turboprops. This additional fleet is referred to as the 37.5M High RJ Fleet. In terms of operation levels, the 37.5M High RJ Fleet falls between the 37.5M Low and High Fleets.[2] For the purposes of assessing delay, the delay model inputs reflect the recommendation of a separate evaluation by the FAA's consultant regarding the use of the proposed runway by the RJ Fleet. Those assumptions are discussed in Chapter 4 of this Supplemental DEIS/FEIR. The delay reduction results of all five Alternatives (Alternatives 1, 1A, 2, 3, and No Action) under the 37.5M High RJ Fleet are included at the end of Chapter 4.

As part of the preparation of this FEIR, the EOEA Secretary instructed Massport to complete several analyses that would allow a more complete evaluation of Peak Period Pricing including a Peak Period Monitoring System and an Exemption Program for communities dependent on Logan Airport. Although Massport does not recommend immediate implementation of Peak Period Pricing as part of the Preferred Alternative, the Authority recognizes the potential delay reduction benefits associated with Peak Period Pricing in an environment of airline overscheduling. Massport is prepared to implement Peak Period Pricing when necessitated by airline overscheduling. In Chapter 4 of this Supplemental DEIS/FEIR, Massport proposes a tightly crafted exemption program that would protect greatly affected communities from losing connections to the national air transportation system. Incorporating a small community exemption program is intended to reduce the expected degree of service disruptions resulting from Peak Period Pricing, without undermining the program's delay reduction benefits. Chapter 4 of the Supplemental DEIS/FEIR presents a Peak Period Monitoring program designed by Massport to determine when airline scheduling may become problematic. The EOEA Secretary also suggested that specific analysis be conducted to determine whether a peak period surcharge could have the adverse impact of encouraging "increased reliance on early morning and late evening flights." Chapter 4 of this Supplemental DEIS/FEIR also discusses the potential for alterations in the regional airline fleet mix resulting from Peak Period Pricing.

At the FAA's and the EOEA Secretary's request, Massport broadened the discussion of the Preferential Runway Advisory System (PRAS) by providing further context to the PRAS Program. Chapter 4 of this Supplemental DEIS/FEIR examines land use patterns and residential densities among the affected communities, in order to

2 The proposed Airside Project improvements were evaluated against a near-term demand level of 29 million annual passengers and long-term levels of 37.5 and 45 million passengers. These demand levels are expected in the years 2003, 2015, and 2024, respectively, and at each passenger level, two different operations forecasts were developed. The High and Low scenarios, presented in the Airside Project Draft EIS/EIR, reflect differing fleet mix assumptions. The Low fleets assume more large jet operations than non-jet operations, similar to current conditions. The High fleets assume a greater proportion of non-jet aircraft and thus a higher level of total operations for the same passenger level.

determine whether they have remained relatively unaltered since the PRAS Program was initially developed. Chapter 4 also examines historic PRAS achievement, in order to determine its utility as a part of the baseline for the No Action Alternatives. The chapter also describes current PRAS monitoring practices and details specific Massport commitments for more frequent and comprehensive PRAS monitoring and public reporting.

An important goal of PRAS is to route flights over the water between 12:00 AM and 6:00 AM. The EOEA Secretary requested that Massport examine the potential for extending the nighttime hours for routing aircraft over water. Chapter 4 of this Supplemental DEIS/FEIR examines the feasibility of extending this preferential nighttime routing policy.

The concept of restricting the availability and use of Runway 32 to northwest wind conditions only was discussed during the SDEIS Panel process. Appendix D addresses the impact of such a restriction on delay reduction, runway utilization and PRAS achievement. This analysis was conducted under the 37.5M High RJ Fleet scenario.

- **Chapter 5: Affected Environment** – In the Airside Project Draft EIS/EIR, Chapter 5 presented an overview of the baseline environmental conditions within the airport and surrounding communities. In Chapter 5 of this Supplemental DEIS/FEIR, the analysis of baseline conditions was expanded to include evaluation of the current environmental conditions that were presented in the *1998 Annual Update*.[3] Chapter 5 was also modified to include a description of historic properties and parklands within the project impact area (this material was previously contained in Chapter 8 of the Airside Project Draft EIS/EIR) to support the analysis of potential impacts regulated under Section 4(f) of the Department of Transportation Act, and under Section 106 of the National Historic Preservation Act of 1966, as amended.

- **Chapter 6: Environmental Consequences** -- In the Airside Project Draft EIS/EIR, Chapter 6 described the potential benefits and impacts of each alternative with regard to social, cultural and environmental resources. Chapter 6 of this Supplemental DEIS/FEIR repeats much of this analysis, but focuses the comparison between the Preferred Alternative (all actions except Peak Period Pricing) and the No Action Alternative for the 29 million passengers[4] (29M) Low and the 37.5 million passengers[5] (37.5M) High fleets. These fleets were chosen because the 29M Low reflects the worst case in terms of noise, and together they represent the full range of potential impacts. In addition, the environmental impacts associated with each alternative for the 37.5M High RJ Fleet are included for review in this Supplemental DEIS/ FEIR. The remaining alternatives are presented in the Airside Project Draft EIS/EIR and repeated again in Appendices E and F of this Supplemental DEIS/FEIR.

3 *Boston-Logan International Airport:1998 Annual Update*, October 15, 1999.
4 The Low operations fleet scenarios assume more large jet operations than non-jet operations, similar to current conditions.
5 The High operations fleet scenarios assume a greater proportion of non-jet aircraft and thus a higher level of total operations for the same passenger level.

To provide further clarity for the affected areas, the noise analysis is presented through Geographic Information System (GIS) mapping with a more detailed base map and a different scale than was presented in Chapter 6 of the Airside Project Draft EIS/EIR. For the Preferred Alternative, the numbers and locations of people who are exposed to noise in the No Action Alternative or who will be exposed to each 5 decibel (dB) increment of noise exposure from Day-Night Sound Level (DNL) values of 60 to 70 dB, and the number and location of people who are expected to shift into a different 5 dB increment of exposure, are presented in tabular and graphical form. These results are reported for people who experience increases as well as decreases in noise exposure. This Supplemental DEIS/FEIR also includes the noise contours and noise-exposed populations for Alternatives 1, 1A, 2, 3, and 4 for the 37.5M High RJ Fleet.

Chapter 6 of this Supplemental DEIS/FEIR discusses the relationship between the Airside Project analysis and FAA's *Runway 27 EIS*.[6] Chapter 6 was modified from the Airside Project Draft EIS/EIR to include a description of historic properties and parklands within the Airside Project impact area and a summary of potential impacts and mitigation. This material was previously contained in Chapter 8 of the Airside Project Draft EIS/EIR. In response to the FAA's additional work tasks for the SDEIS, Appendix E includes a school year/school day 65 dB DNL contour for the Preferred Alternative for the 29M Low Fleet.

In the Airside Project Draft EIS/EIR, the Environmental Justice analysis was presented in Chapter 8. In response to comments received on the Airside Project Draft EIS/EIR from the EPA Region 1 and others, the presentation of Environmental Justice has been significantly expanded. Chapter 6 of this Supplemental DEIS/FEIR (Section 6.8) includes a discussion of Environmental Justice requirements and additional Environmental Justice analyses requested by the EOEA Secretary. The Environmental Justice discussion includes more detailed demographic data presented in both tabular and GIS map formats; an analysis of impacts at the 60 dB level, as requested by the EOEA Secretary; a comparison of the affected population with that of Boston and other affected municipalities; a discussion of other environmental and health effects in accordance with CEQ guidance; and a discussion of the community participation process followed for review of the Airside Project. Finally, the discussion and depiction of flight paths is enhanced to show additional geographic coverage.

- **Chapter 7: Cumulative Impacts** – In the Airside Project Draft EIS/EIR, Chapter 7 presented an assessment of incremental environmental impacts of the alternatives in the context of other past, present, and reasonably foreseeable projects. Chapter 7 of this Supplemental DEIS/FEIR presents an updated construction management plan that quantifies the number of daily and total truck trips expected in connection with the Airside Project and any other major construction activities planned to occur in East Boston.

6 Runway 27 Environmental Impact Statement, prepared by the FAA, issued June 1996.

- **Chapter 8: Preferred Alternative and Mitigation** – Chapter 8 describes Massport's project specific mitigation measures which include:

  - Commitments to reinforce the unidirectional use restriction on Runway 14/32.
  - Sound insulation for eligible residences located within the Preferred Alternative 65 dB DNL contour for the 29M Low Fleet scenario.
  - Relocation assistance for the airport tenants affected by construction of Runway 14/32.
  - Habitat enhancement for the state-listed endangered upland sandpiper.
  - Construction mitigation measures including participation in the Clean Air Construction Initiative.

  In addition to project specific mitigation, the May 7, 1999 EOEA Certificate required Massport to commit to a number of "concrete mitigation measures…that will maintain or reduce the existing envelope of cumulative environmental impacts from airport operations." Specific measures identified by the EOEA Secretary that are addressed in this Supplemental DEIS/FEIR include:

  - Steps to be taken by Massport and other state transportation agencies to ensure that the Worcester, Manchester and T.F. Green/Providence airports operate jointly with Logan Airport as the key elements in an efficient and environmentally balanced regional air transportation network.
  - Regular monitoring of peak period airline schedules and delays and definition of the appropriate conditions at which Massport will implement a Peak Period Pricing Program.
  - Protocols for monitoring adherence to the PRAS goals and periodic disclosure of monitoring results.
  - Massport and the FAA will continue to complete the current 2-year sound insulation program as presented in the *Logan Airport 1999 Environmental Status and Planning Report*.
  - Specific noise mitigation commitments to minimize nighttime noise.
  - Work with air carriers to reduce the use of noisier "hushkitted" aircraft at Logan Airport.

Chapter 8 also includes Massport's Draft Section 61 Findings under MEPA. A comparison between the chapters of the Airside Project Draft EIS/EIR and this Supplemental DEIS/FEIR is provided in Table P-1. Table P-2 outlines the analysis tasks required by the FAA following the SDEIS Panel process. To assist the reader, the table outlines where these analyses are located within this Supplemental DEIS/FEIR.

Table P-1
Airside Project
Comparison between the Airside Project Draft EIS/EIR and this Supplemental DEIS/FEIR

Chapter		Airside Project Draft EIS/EIR	Supplemental DEIS/FEIR
1	Project Background, Purpose and Need	■ Project overview ■ Foundation of analyses ❑ Logan's role in the regional economy ❑ Passenger volumes and aircraft operations ❑ Delays at Logan, and cost implications ❑ Logan's operations	■ Summary of key points from the Draft EIS/EIR ■ Comprehensive discussion of delays at Logan ■ Comparison of Logan to other United States airports in terms of delay ■ Analysis of Logan delays caused elsewhere in the system ■ Analysis of Logan's national delay ranking if Runway 14/32 were available
2	Logan's Role in the Regional Transportation System	■ Effects of regional alternatives (regional airports and rail) to Logan on projected air passenger demand ❑ Regional transportation context and role of Logan ❑ Role of alternative travel choices ❑ Report on support for regional alternatives	■ Summary of key points from the Draft EIS/EIR ■ Expanded regional transportation analysis ■ Discussion of changing role of Logan, T.F. Green/Providence, Manchester, and Worcester airports ■ Quantitative analysis of potential relief provided by Worcester Regional Airport ■ Impact of regionalization on Logan demand forecasts ■ Report on status of proposed ground access improvements at Logan, Manchester, T.F. Green/Providence, and Worcester airports ■ Report on existing studies relating to environmental impacts associated with continued growth at regional airports (Refer to Appendix B for additional information) ■ Describe planned New England Airports System Study
3	Alternatives	■ Detailed description of concepts and alternatives analyzed ❑ Unidirectional Runway 14/32 ❑ Taxiway Improvements ❑ Reduced Approach Minimums ❑ Peak Period Pricing ❑ Alternative Packages	■ Summary of key points from the Draft EIS/EIR ■ Detailed discussion of PACE program, and its relevance to Peak Period Pricing ■ Discussion of demand management strategies used by other airports ■ Clarification of Centerfield Taxiway on taxiway queuing

Table P-1 (Cont'd.)
Airside Project
Comparison between the Airside Project Draft EIS/EIR and this Supplemental DEIS/FEIR

Chapter	Airside Project Draft EIS/EIR	Supplemental DEIS/FEIR
4 Delay Analysis	■ Discussion of passenger and aircraft operations forecasts and assumptions ❑ Passenger and Aircraft Operations Forecasts ❑ Delay Modeling Approach ❑ Peak Period Pricing ■ Aircraft Delay and Runway Use Results	■ Summary of key points from the Draft EIS/EIR ■ Clarification of use of 1993 Historic Modeled as baseline condition ■ Description of additional analysis condition - 1998 Existing Condition, based on the 1998 Annual Update ■ Discussion of new 37.5M High RJ Fleet ■ Evaluation of current assessment of delay levels at Logan (1998) ■ Expanded evaluation of Peak Period Pricing ■ Consideration of small-community exemption program ■ Discussion of potential for alteration in the regional airline fleet mix result from Peak Period Pricing. Broadened discussion of PRAS program including examination of land use patterns and residential densities in affected communities ■ Examination of historic levels of PRAS achievement ■ Examination of feasibility of extending PRAS nighttime hours ■ Operational analysis of 37.5M High RJ Fleet ■ Discussion of potential northwest wind use restriction on Runway 14/32
5 Affected Environment	■ Overview of baseline (1993 historic modeled) environmental condition within the airport and surrounding communities ❑ Noise ❑ Air Quality/Odors ❑ Ecosystems ❑ Water Quality ■ Soil/Sediment Characterization	■ Summary of key points from the Draft EIS/EIR ■ Comparison of environmental conditions for the 1993 historic modeled conditions with 1998 actual conditions (based on the findings of the *1998 Annual Update*) ■ Addition of description of historic properties and parklands within the project impact area (formerly in Chapter 8 of the Airside Project Draft EIS/EIR)

Table P-1 (Cont'd.)
Airside Project
Comparison between the Airside Project Draft EIS/EIR and this Supplemental DEIS/FEIR

Chapter	Airside Project Draft EIS/EIR	Supplemental DEIS/FEIR
6 Environmental Consequences	■ Description of potential benefits and impacts of each alternative with regard to social, cultural, and environmental resources ❑ Land Use and Social Impacts ❑ Noise ❑ Air Quality/Odors ❑ Ecosystems ❑ Water Resources ❑ Soil/Sediment Impacts ❑ Construction Impacts	■ Summary of key points from the Draft EIS/EIR ■ Review of potential benefits and impacts of each alternative, but with a focused comparison of the Preferred Alternative (all actions except Peak Period Pricing), to the No Action Alternative ■ Analysis of environmental benefits and impacts of a 37.5M High RJ Fleet ■ GIS mapping with a more detailed base map showing land use at a larger scale ■ Tabular and graphic comparison of the Preferred Alternative and No Action Alternative showing the number and location of people who are exposed to noise ■ Discussion of the relationship between the analyses conducted for the Airside Project and the Runway 27 EIS ■ Focused noise contour analysis comparing the 1998 Annual Update, Runway 27 EIS, and the Airside Project noise contours ■ Discussion of environmental justice ■ Addition of description of historic properties and parklands within the project impact area and a summary of potential impacts and mitigation (formerly in Chapter 8 of the Airside Project Draft EIS/EIR) ■ Inclusion of a school day/school year noise contour for the Preferred Alternative under the 29M Low Fleet scenario

Table P-1 (Cont'd.)
Airside Project
Comparison between the Airside Project Draft EIS/EIR and this Supplemental DEIS/FEIR

Chapter		Airside Project Draft EIS/EIR	Supplemental DEIS/FEIR
7	Cumulative Impacts	■ Assessment of incremental environmental impacts of the alternatives in the context of other airport landside projects ■ Comparison of the interrelationship/independence of Massport's airside and landside initiatives ❑ Relationship to GEIR ❑ Relationship to Logan Projects ❑ Long-term Cumulative Effects ❑ Construction Impacts	■ Updated construction management plan ■ Quantification of the number of daily and total truck trips (including simultaneous construction activity with the CA/T, other Logan projects, and planned East Boston projects)
8	Preferred Alternative and Mitigation	■ Updated construction management plan. ■ Summary of Delay Reduction ■ Summary of Environmental Impacts ■ Preferred Alternative Impacts and Mitigation ■ Compliance with Cultural Resources Laws ■ Environmental Justice ■ Permits	■ Proposed Mitigation: Massport ❑ Specific steps to be taken by Massport (and others) to ensure that Worcester, Manchester and T.F. Green/Providence airports work with Logan in a balanced regional air network ❑ Regular monitoring of peak period airline schedules ❑ A protocol to monitor PRAS goals adherence ❑ Sound insulation of homes eligible as a result of the Airside Project ❑ Progress on working with the air carriers to limit the use of "hushkitted" aircraft ❑ Reinforcement of unidirectional use restriction on Runway 14/32 ❑ Provide relocation assistance to affected airfield tenants ❑ Habitat enhancement for upland sandpiper ❑ Construction mitigation measures ❑ Participation in the Clean Air Construction Initiative ❑ Inclusion of Massport's Draft Section 61 Findings ■ Proposed Mitigation: FAA ❑ Sound Insulation

Airside Project
Additional Analyses for the Supplemental DEIS/FEIR

Task		Action	Location in Document
1	Is a 5,000-foot Runway 14/32 effective given the expected use of regional jets in the future fleet mix?	■ Verify and confirm previous survey of airlines and manufacturers to determine minimum arriving /takeoff distances for regional jet aircraft. ■ Research regional jet aircraft usage and runway length requirements at other airports. ■ Review forecast mix of regional jet aircraft types at Logan. ■ Develop estimate of probable regional jet utilization of a 5,000 foot Runway 14/32.	Chapter 4 and Appendix C
2	Expand Regionalization analysis contained in Interim Supplemental Draft EIS	■ Discuss proposed New England Airports System Study and proposed work scope. ■ Update status of traffic and services at the regional airports, Amtrak's Acela service, and ground access projects. ■ Add historical context and on-going nature of regionalization efforts.	Chapter 2

Table P-2 (Cont'd.)
Airside Project
Additional Analyses for the Supplemental DEIS/FEIR

Task		Action	Location in Document
3	Expand analysis of peak period pricing.	■ Review changes in airline scheduling activity at Logan and assess how and why the demand profile has flattened over time. ❑ Determine which new airline/markets have contributed to changes in the demand profile. ❑ Assess whether the flattened profile or a more peaked profile is likely to occur in the new future fleet (37.5M High RJ Fleet).	Chapter 4
		■ Discuss the design of a Peak Period Pricing program that would impact regional jet scheduling practices at Logan. ❑ Base analysis on 37.5M High RJ Fleet, using an updated demand profile and a small community exemption program. ❑ 3.2.2 Discuss the economic cost of Peak Period Pricing to the consumer. ❑ 3.2.3 Discuss the uniqueness of Cape Air and the communities that it serves.	Chapter 4
		■ Identify known, comparable demand management strategies that are in use or have been proposed by other airports.	Chapter 4
4	What impact does the 2015 Modified 37.5M RJ fleet mix have on delay reduction benefits and environmental impacts?	■ Develop 2015 fleet mix and demand profile assuming 37.5M passengers and increased RJ utilization.	Chapter 6
		■ Assess the impacts of the new fleet on delays, runway utilization, noise contours and noise-exposed populations for Alternatives 1, 1A, 2, 3 and 4.	Chapter 4 and Chapter 6

1 Project Background, Purpose, and Need

Key Points

In 2000, Boston-Logan International Airport (Logan), the nation's 18th busiest airport, handled 27.4 million air passengers with 479,000 aircraft operations. Logan suffers from a serious aircraft delay problem and is consistently ranked among the most delayed airports in the country. Current delays at Logan are principally attributable to adverse wind and weather conditions that can produce a significant decline in Logan's airfield capacity. Logan is the 6th most delayed airport in the nation and, because of a limitation in the existing runway layout, it fares even worse in arrival delays, ranking as the 2nd most delayed airport in the nation. Logan's delay problem will only worsen as future levels of aircraft operations grow.

Chapter 1 of the *Airside Improvements Planning Project Draft Environmental Impact Statement/ Environmental Impact Report* (Airside Project Draft EIS/EIR)[1] together with Chapter 1 of this Supplemental Draft Environmental Impact Statement/Final Environmental Impact Report (Supplemental DEIS/FEIR) provides the purpose and need for the Airside Improvements Planning Project (Airside Project). In response to a number of substantive comments on the Airside Project Draft EIS/EIR, including those of the Federal Aviation Administration (FAA), the SDEIS Panel[2] and the Secretary of the Executive Office of Environmental Affairs (EOEA), this chapter provides historic context for Logan's delay problem; compares Logan to other major US airports; and provides a more comprehensive discussion of delays. This chapter broadens the discussion of delays to include not only those that are caused by Logan, but also those incurred by Logan passengers but caused by conditions at other airports. At the FAA's direction, based on input received from the SDEIS Panel, this chapter also assesses the effect that the availability of proposed Runway 14/32 would have had on Logan's current national delay ranking.

- Logan currently experiences approximately 142,000 annual hours of delay (120,000 hours runway delay and 22,000 hours taxiway delay), which is more than seven times the FAA's threshold for congestion.
- Logan delays are estimated to cost airlines and passengers more than $300 million annually.
- There are multiple causes of aircraft delays at Logan and nationwide. Solving such a complex problem requires a multifaceted solution. There is no single measure that will

▼

1 *Logan Airside Improvements Planning Project Draft EIS/EIR*, prepared by Massport and the FAA, February 1999.

2 In January 2000, in response to the FAA's review of the Draft EIS, the FAA called for preparation of a Supplemental Draft EIS. At the FAA's direction, a Supplemental DEIS Panel was formed. The panel consisted of three members appointed by the Governor of the Commonwealth of Massachusetts and three members appointed by the Mayor of the City of Boston.

resolve all aircraft delays at Logan. Each cause of delay requires a unique solution and no single solution diminishes the need for other solutions.

- The principal cause of delay at Logan is the substantial drop in airfield capacity that occurs when wind and weather conditions force air traffic controllers to utilize configurations with fewer than three runways.
- Further, the lack of a third available runway in the east-west operating direction causes an imbalance in the geographic distribution of jet operations at Logan. Approximately three-quarters of Logan's jet flights overfly communities impacted by use of north and south runway configurations. Under high demand scenarios, if no actions are taken, Logan's reliance on north/south runway configurations will increase to over 90 percent. The proposed new runway (Runway 14/32) would allow for a more balanced distribution of future operations, with 41 percent in the north/south directions, 29 percent to the west and 30 percent over the water.
- The following solutions to ease airside delays at Logan are proposed:
  - Construct unidirectional Runway 14/32 to address one of the major causes of delay, strong northwest winds, by providing a third active runway in conditions that now require Logan to operate on two or fewer runways. This runway will provide a second arrival stream and prevent the decline in airfield capacity that currently occurs. All flights using the new Runway 14/32 will arrive or depart over Boston Harbor, and the additional three-runway configuration will provide an opportunity for better achievement of the long-term and short- term Preferential Runway Advisory System (PRAS)[3] goals that are designed to equitably distribute impacts among affected communities.
  - Construct taxiway improvements to reduce taxiway congestion and the potential for runway incursions, thereby enhancing the general safety of airside operations. The taxiway improvements will facilitate more efficient movement between the terminal areas and the runways during takeoff and landing procedures and will reduce the associated levels of aircraft delay.
  - Reduce approach minimums for Runways 15R, 22L, 27 and 33L to increase the availability of these runways, reduce reliance on Runway 4R in low visibility and enhance safety under adverse operating conditions. The Runway 22L and Runway 27 minimums will be reduced to levels consistent with the capabilities of the existing electronic navigational equipment, while approaches to Runways 15R and 33L will be upgraded to Category III Instrument Landing Systems (ILSs).
  - Promote increased utilization of regional airports and highspeed rail to accommodate a greater share of the region's intercity travel demand.

3 The Preferential Runway Advisory System (PRAS) is a computer program that recommends to the FAA air traffic controllers runway configuration options that will meet weather and demand requirements, while providing an equitable distribution of the airport's noise impacts. The primary objectives of PRAS are to distribute aircraft operations in accordance with annual runway utilization goals, and to provide short-term relief from continuous operations over the same neighborhoods.

- In addition to project-specific mitigation, Massport has developed other mitigation commitments including:
  - To address possible delays caused by airline overscheduling, Massport has designed a Peak Period Monitoring System and is committed to initiating a Peak Period Pricing program when and if it is needed.
  - Massport and the FAA cannot entirely eliminate delays at Logan. However, by correcting a shortcoming in Logan's existing airfield layout and by closely monitoring and managing demand, they can significantly reduce delays at Logan.

1.1 Purpose and Need

By all accounts, the air transportation industry is currently suffering from a record number of flight delays. According to the US Department of Transportation (US DOT), 27.4 percent of airline flight arrivals in 2000 were delayed by more than 15 minutes, and Logan was one of the most delayed airports in the nation.[4] According to FAA statistics, Logan was the 6th worst US airport in terms of total delays and the 2nd worst in terms of arrival delays.[5]

The national delay problem is so severe that it threatens the nation's productivity and undermines economic growth. According to the US Secretary of Transportation, "One of the greatest challenges faced by the Department of Transportation, the FAA and the commercial aviation industry is to close the gap between demand for air transportation and the capacity of our current infrastructure. We cannot afford to delay the work."[6] He also commented that the nation's air transportation system faced gridlock in the year 2000, and that while there is no quick fix to the problem of aviation congestion, airlines, airports, and air traffic control must work together to develop innovative solutions.

The Airside Project identifies physical improvements and actions that address very specific causes of delay at Logan Airport. The improvement concepts that were evaluated in the Airside Project Draft EIS/EIR and this Supplemental DEIS/FEIR are summarized in Table 1.1-1. Proposed airside improvement concepts are designed to enhance Logan's operating efficiency and safety by reducing current and projected runway and taxiway delays.

Table 1.1-1
Purpose of Airside Improvement Concepts

Improvement Concept	Purpose
Construct Unidirectional Runway 14/32	Reduce Northwest Wind Delays
Peak Period Pricing	Reduce Overscheduling Delays
Construct Centerfield Taxiway	Reduce Taxiway Delays, Enhance Safety
Extend Taxiway Delta	Reduce Taxiway Delays, Enhance Safety
Realign Taxiway November	Simplify Taxiway System, Enhance Safety
Optimize Southwest Corner Taxiways	Reduce Taxiway Delays, Enhance Safety
Reduce Approach Minimums on Runways 22L, 27, 15R and 33L	Provide for Safer Instrument Approaches

As the gateway to New England, Logan plays a vital role in the region's current and future economic prosperity by ensuring fast and efficient access to the global marketplace. Delays at Logan cause an estimated $300 million in unnecessary costs to airlines and air passengers annually. In 2000, Logan accommodated 27.4 million passengers, representing more than 60 percent of all New England air passengers. Logan is the 18th busiest US airport based on passenger volume and the 12th busiest based on aircraft operations (arrivals and departures).[7]

The aircraft delays that plague Logan hamper the airport's ability to provide efficient and reliable access to national and world markets and threatens the region's long-term economic success.

The Airside Project Draft EIS/EIR analysis demonstrated that a large portion of the aircraft delays at Logan are avoidable and can be eliminated by correcting a limitation in the airport's existing runway layout. Approximately one-fourth of the annual aircraft delays at Logan occur during periods of northwest winds. While Massport and the FAA cannot resolve certain causes of delay, such as inclement weather, they can act to reduce delays that occur in northwest wind conditions by improving Logan's airfield layout. Most often, Logan is able to operate on three-runway configurations that can accommodate approximately 120 operations per hour. However, moderate to strong northwest winds can restrict the airport to low-capacity configurations with two or fewer runways that accommodate only 60 to 90 operations per hour. When these configurations are in use, Logan cannot accommodate normal levels of demand without incurring serious delays.

The proposed unidirectional Runway 14/32 is designed to increase the reliability of Logan Airport by preventing the decline in capacity that occurs during northwest winds. By allowing Logan to maintain its normal operating capacity, Runway 14/32 would significantly reduce these preventable delays.

7 Airports Council International, *Worldwide Airport Traffic Report,* July 2000.

Delays at Logan can also accrue when airlines schedule beyond the airport's normal runway capacity (120 operations per hour). In the early 1990s, airline overscheduling was a significant source of flight delays at Logan. At that time, Massport seriously considered establishing a peak period pricing program to eliminate airline overscheduling and related flight delays. However, these conditions subsided when one of Logan's three major regional airlines ceased operations, producing an immediate reduction in flight volume.

Logan does not currently suffer from airline overscheduling. However, Massport recognizes that overscheduling conditions could re-emerge in the future and exacerbate Logan's delay problem. The Airside Project analysis includes an evaluation of Peak Period Pricing as a delay reduction measure across a range of future operating conditions (see Chapter 4). The analysis indicates that Peak Period Pricing would be effective in reducing delays when the airport suffers from airline overscheduling. However, Peak Period Pricing would not address delays caused by northwest winds. Massport has designed a Peak Period Monitoring System to identify overscheduling conditions and would initiate a Peak Period Pricing program if and when conditions warrant such action.

In addition to improvements that are designed to relieve airside delays, Massport and the FAA examined potential improvements to Logan's complex taxiway system. The proposed taxiway improvements would increase airfield efficiency and decrease taxiway delays by simplifying the existing taxiway system. The taxiway improvements would also enhance safety by reducing the risk of runway incursions.

The Supplemental DEIS/FEIR focuses on the comparison of the Preferred Alternative (Alternative 1A) to the No Action Alternative (Alternative 4) for two of the fleets that were analyzed in the Airside Project Draft EIS/EIR.[8] Table 1.1-2 summarizes the combinations of improvement concepts, or "project alternatives," that were evaluated under five future fleet scenarios in the Airside Project Draft EIS/EIR. This Supplemental DEIS/FEIR focuses the analysis on the 29M Low Fleet, the 37.5M High Fleet, and the additional 37.5M High Regional Jet (RJ) fleet, which is evaluated for all Project Alternatives.

8 Appendices C, E and F of this Supplemental DEIS/FEIR contain the operational and environmental results for the full set of alternatives which were described in detail in the Airside Project Draft EIS/EIR

Table 1.1-2

Reduced Minimums	■	■	■	■	
Peak Period Pricing	■		■	■	

After careful review in the Airside Project Draft EIS/EIR of the extent and causes of delays at Logan and the comparative benefits of each alternative, Alternative 1A was selected as the Preferred Alternative because it would significantly reduce delay without imposing unnecessary economic costs on regional carriers and New England communities adversely affected by Peak Period Pricing. Additionally, the Preferred Alternative would achieve certain environmental benefits, including improved air quality and a reduced noise exposure for the most severely affected communities, while causing minimal environmental impacts, all of which would be mitigated.

In the Airside Project Draft EIS/EIR, Chapter 1 served as an introduction and provided the foundation for the project's purpose and need. In this Supplemental DEIS/FEIR, Chapter 1 summarizes the project purpose and need and clarifies the issues of delay and the extent of Logan Airport's delay problem. Specifically, this chapter contains a more comprehensive discussion of airport delays, provides historical context for Logan's delay problem, and compares Logan's performance to other major US airports.

This analysis further confirms the need for the Preferred Alternative. This chapter also presents additional analyses identified by the FAA as a result of the SDEIS Panel process. These include a discussion of delays at Logan that are caused by other airports and the delay reduction benefits that Runway 14/32 would have produced if the runway had been operational in 1998.

1.2 How Logan Operates

Airfield capacity is a function of airport design (the number and direction of runways and taxiways, runway instrumentation, etc.), weather conditions (visibility and wind

direction), aircraft mix (heavy, large, small), and FAA Air Traffic Control (ATC) procedures that govern the sequencing and spacing of aircraft. Thus, even for a given airfield layout, capacity is a dynamic factor that varies with changes in wind direction, weather conditions and the mix of arriving and departing aircraft.

1.2.1 The Airfield Layout

Logan's airfield layout, illustrated in Figure 1.2-1, consists of five runways, which vary in length from 2,557 feet to 10,081 feet.[9] Logan's runways are aligned in three directions with runway ends pointing toward six distinct compass headings. Aircraft must generally takeoff and land into the wind, so the availability of specific runway configurations is determined by wind speed and direction, and other weather conditions. The runway layout provides necessary operating flexibility given Logan's coastal location and highly variable wind conditions. Non-coastal airports that do not experience the same variation in wind conditions generally have a simpler airfield layout and fewer required operating configurations.

1.2.2 Runway Use Configurations

While Logan has five runways, typically no more than three runways can be used concurrently. Delays occur when only low capacity configurations (i.e., less than three active runways) are available and flight demand exceeds available capacity. To operate efficiently under all wind directions, Logan requires three active runways for most of the operating day.

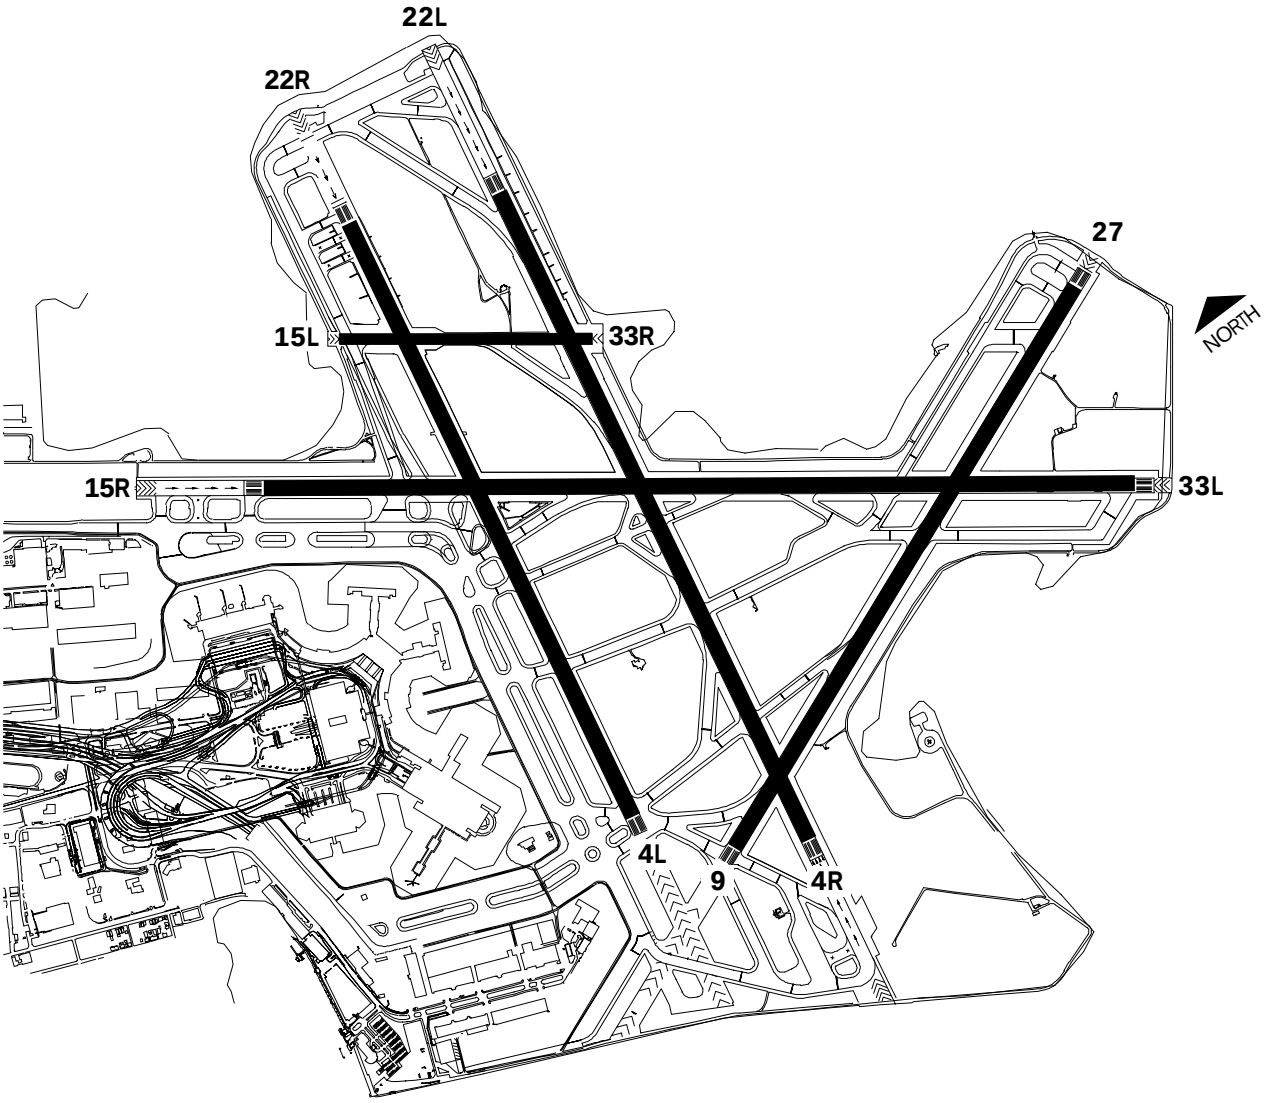
There are several primary runway configurations in use at Logan, with over 80 operating subsets of these configurations. As described in the Airside Project Draft EIS/EIR, the operational capacities of Logan's existing configurations range from a maximum of approximately 120 operations per hour when the weather is good, winds are light, and three runways are available, to fewer than 60 hourly operations for a single runway.

Logan's highest capacity configurations have three active runways which allow FAA controllers to segregate arriving aircraft of different size classes into two arrival streams and to use the third runway for aircraft departures. High capacity runway configurations are available at Logan nearly 80 percent of the year. For the remaining part of the year, poor wind and weather conditions restrict the airport to low capacity configurations with just one or two available runways.

9 Logan's shortest runway, Runway 15L/33R, has very limited utilization and can only be used by the smallest-sized aircraft, e.g., Cessna 402s with 9 seats.

As shown in Figures 1.2-2 to 1.2-3, the north-south configurations are the highest capacity configurations at Logan. These configurations include the Runways 4L, 4R, and 9 configuration and the Runways 22L, 22R, and 27 configuration. With three available runways, these configurations maximize the airport's operating efficiency by providing two runways for arriving aircraft, which permits air traffic control to segregate aircraft of different size classes. Conversely, when the airport is restricted to a two-runway or one-runway configuration with a single arrival stream, this type of segregation cannot occur. As shown in Figures 1.2-4 to 1.2-6, Logan is restricted to two or one runway when operating in an east / west orientation. These low capacity configurations include the east / southeast configuration of Runways 15R and 9, and the west / northwest configuration using Runways 27 and 33L. Under very strong northwest winds, Logan can be restricted to just a single runway, Runway 33L, to handle all arriving and departing aircraft.

Because Logan lacks a third available runway in the east-west direction and Runway 15L / 33R is too short to be used by most aircraft, the north-south runway configurations are utilized most frequently (see Figure 1.2-7). In 1998, 76 percent of Logan's jet operations landed on or departed from the north / south runway configurations (Runways 4L and 4R arrivals, 4R departures, Runway 9 departures, 22L and 22R departures, and 22L and 27 arrivals). As a result, communities affected by the north / south runway configurations bear a disproportionate share of jet overflights. Conversely, 11 percent of Logan's 1998 jet operations were on runways affecting communities west of the airport (Runway 27 and 33L departures, and 15R arrivals) and 13 percent utilized over-the-water runways (15R for departures and 33L for arrivals).



RUNWAY LENGTH DATA (feet)

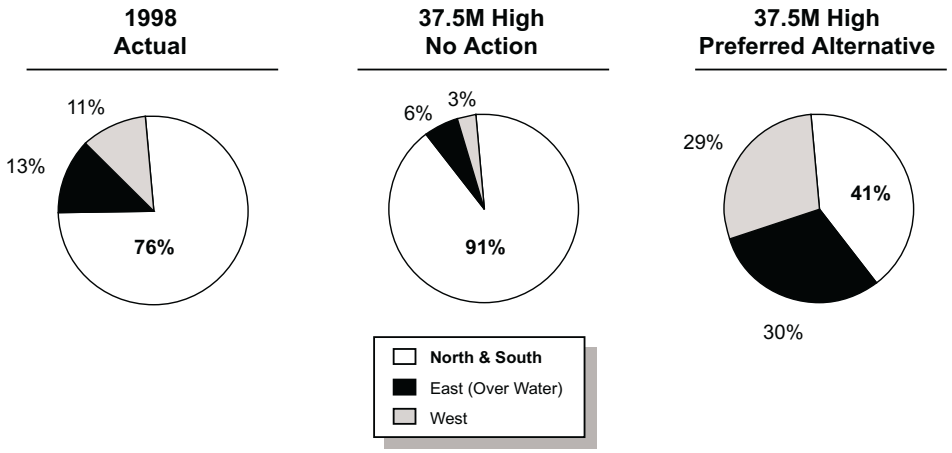
Figure 1.2-7 shows that if no action is taken to correct this limitation in the airfield layout, Logan's dependence on north-south runways will increase to more than 90 percent under the 37.5M High Fleet[10] scenario. With construction of proposed Runway 14/32, Logan's dependence on north-south configurations would decline to 41 percent. By making a third runway available in the east-west operating direction, the Preferred Alternative allows for a more balanced geographic distribution of jet overflights – 41 percent north/south, 30 percent east (over water), and 29 percent west.

Figure 1.2-7
Geographic Distribution of Jet Flights at Logan



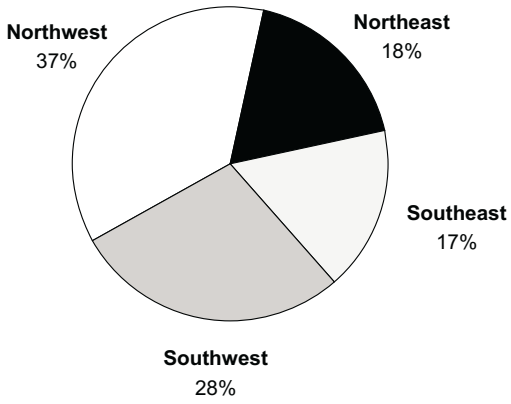
1.2.2.1 Impact of Wind and Weather Conditions on Airport Capacity

When weather conditions deteriorate, wind direction shifts to the northwest, or winds intensify, Logan is reduced to operating with only one or two active runways. A major limitation of Logan's airfield is the lack of a three-runway configuration in the northwest/southeast orientation. Even under clear weather conditions, northwest winds can create a situation in which a three-runway configuration is unavailable. Air traffic control procedures and other restrictions may further reduce the capacity of the one- or two-runway operating configurations. As a result, even when aircraft demand levels are moderate, delays can reach severe levels if wind or weather dictates the use of low capacity configurations.

10 The High Fleet assumes a greater proportion of non-jet aircraft and thus a higher level of total operations for the same passenger level than the Low Fleet, which assumes more large jet operations than non-jet operations, similar to current conditions.

Figure 1.2-8 illustrates the percentage of time that winds from different directions occur at Logan during a typical year. In light winds and good visibility, high capacity three-runway configurations are generally available. With moderate northeast and southwest winds, Logan can also operate on high capacity runway configurations. With northeast winds, the Runways 4L, 4R and 9 configuration is available for use (see Figure 1.2-2). When wind direction shifts to the southwest, the Runways 22L, 22R and 27 configuration is used (see Figure 1.2-3).

Figure 1.2-8
Typical Yearly Wind Direction at Logan



Wind-related delays become significant when moderate to strong winds originate from the northwest, the most common wind direction at Logan. Because northwest winds usually coincide with clear, visual flight rules (VFR) weather conditions, operations could be accommodated with minimal delay if a three-runway configuration were available. In fact, Logan experiences VFR weather conditions 96 percent of the time when winds blow from the northwest. Under moderate northwest winds, Logan is forced to use the low-capacity Runway 27 and 33L configuration (see Figure 1.2-5). Two-runway configurations have an operational capacity of up to 90 operations per hour in VFR conditions.

When northwest winds are especially strong or gusty, Runway 27 cannot be used due to excessive crosswinds. Under these conditions, Runway 33L is the only runway available for both landings and takeoffs (see Figure 1.2-6). Logan's operational throughput is reduced to 60 or fewer operations per hour; aircraft delays become severe and increase exponentially.[11]

11 This condition occurs approximately 10 days per year. See the *Northwest/Southeast Winds Case Study*, Logan Airside Improvements Planning Project Draft EIS/EIR, Appendix I.

1.2.2.2 Impact of Aircraft Mix on Airport Capacity

Logan operates most efficiently when air traffic controllers are able to segregate aircraft of different weight classes into separate arrival streams, allowing shorter separation distances between aircraft. Thus, the highest operating capacities at the airport are achieved when a three-runway configuration is available for use. For example, when the Runways 4L, 4R and 9 configuration is available, Runway 4L is primarily used for non-jet arrivals, Runway 4R is primarily used for jet arrivals and Runway 9 is dedicated to departures.[12] However, when poor weather and/or wind conditions restrict runway availability, controllers are forced to place all aircraft in a single arrival stream, diminishing the airport's capacity. While aircraft are currently limited to a single arrival runway during northwest wind conditions, this would be corrected by construction of the proposed new runway.

When wind and weather conditions force Logan to use a single arrival stream, the mix of aircraft seeking to use the airfield influences the capacity of the airport's runways. For safety reasons, the FAA sets minimum separation standards, which must be maintained between aircraft. All aircraft generate aerodynamic turbulence, known as wake vortices, which trail behind the aircraft in flight. Larger aircraft produce much stronger vortices, which can upset smaller trailing aircraft. Therefore, if smaller aircraft must operate behind larger jets on the same runway, increased separations between aircraft must be maintained. Longer separations reduce the capacity of each runway, since fewer planes can land in a given hour. Because of its role as a regional hub for New England communities and its lack of a dominant jet carrier, Logan exhibits a high proportion of small aircraft operations.

1.2.2.3 Revised Wake-Vortex Turbulence Rules

In response to recommendations by the National Transportation Safety Board, the FAA implemented several revisions to the wake turbulence separations that became effective in 1996.[13] They are discussed in detail in Section 1.2.3.2 of the Airside Project Draft EIS/EIR. These revisions have increased the average separation between arriving aircraft at Logan, and as a result, have decreased capacities and increased delay, particularly during use of two-runway configurations. These changes make it more important for air traffic controllers to be able to segregate aircraft arrival streams at Logan.

12 Runways 4L and 4R also handle some departures.
13 "Safety Issues Related to Wake Vortex Encounters During Visual Approach to Landing," *NTSB Report/SIR-94/01*, February 1994.

1.3 Passenger Volumes and Aircraft Operations

1.3.1 Current Activity and Historic Trends

Logan accommodated 27.4 million air passengers and 479,000 aircraft operations in 2000. More than 60 airlines, including national and international passenger airlines, commuter airlines, and all-cargo airlines, provide direct flights from Logan Airport to over 100 destinations worldwide. In addition to commercial airline services, Logan also handles general aviation activity. In 1999, Logan was the 18th busiest airport in the US in terms of passenger traffic; 12th in aircraft operations; and 19th in cargo tons.[14] Logan functions primarily as an "origin / destination"[15] airport, with 88 percent of passengers originating or terminating at Logan, and only 12 percent of passengers connecting from one flight to another. However, Logan also serves as a regional hub, providing small and isolated New England communities with access to the national airport system. While regional carrier flights carry only a small percentage of total passengers, approximately half of their passengers rely on connections at Logan to reach their ultimate destinations.

Table 1.3-1 provides a summary of air passengers, flight operations, and freight volume from 1980 to 2000. Passenger volume at Logan has increased over time consistent with the increasing levels of air passenger traffic experienced nationwide. However, the rate of passenger growth at Logan has slowed in recent years. Since 1980, passenger traffic at Logan has increased at an average annual rate of 3.1 percent. For the most recent five years (1995 to 2000) Logan passengers grew more slowly, increasing by 2.4 percent annually. In 2000, Logan's passenger traffic increased by just 1.3 percent over the prior year. The observed slow-down in Logan's passenger growth is attributable to the increased role of regional airports and rail as attractive transportation options to Logan Airport.

Aircraft operations at Logan have historically grown at a slower rate than passenger volume due to increases in aircraft size and / or passenger load factors. Between 1980 and 2000, aircraft operations increased at an average annual rate of 2.4 percent. Since 1995 the rate of aircraft operations growth has slowed to 0.6 percent per year. In 1999 and 2000, aircraft operations declined by 2.5 and 3.2 percent, respectively, as regional airlines reduced scheduled services at Logan.

More than 1 billion pounds of freight (cargo and mail) passed through Logan Airport in 2000. Approximately half of Logan's air freight is carried in the belly compartments of passenger aircraft and the remaining half is transported by all-cargo airlines, such as Federal Express and United Parcel Service. In 2000, all-cargo airlines performed approximately 12,000 aircraft operations at Logan, or 2.6 percent of Logan's total operations. Since all-cargo operations primarily occur during off-peak nighttime hours (10:00 PM and 6:00 AM), they do not contribute to aircraft delays at Logan.

▼

14 Airports Council International, Worldwide Airport Traffic Report, 1998.

15 For an "origin/destination" airport, most passengers either originate or terminate their airline journey at that airport. For a connecting airport, a large percentage of passengers stop at the airport as part of their airline journey to transfer from one flight to another.

This Supplemental Draft EIS/FEIR includes updated operational and environmental analyses of 1998 conditions consistent with those described in the *Logan Airport 1998 Annual Update.*[16] While the *Logan Airport 1999 Environmental Status and Planning Report (ESPR)*[17] published in December 2000 includes updated analyses for 1999, the differences between the two study years are small. Between 1998 and 1999, operations declined by 2.5 percent, primarily due to a decline in regional carrier operations.[18] Fleet mix and runway use varied little, and the shape of the noise contours and population impacts were also similar, with slightly less impact in Winthrop and Boston and slightly more impact in Chelsea and Revere in 1999 compared to 1998.[19] The air quality and other environmental analyses also yielded similar results.[20] Since the relevant comparison for evaluating the proposed Airside Project improvements is the comparison between the No Action and Preferred Alternatives, and since 1998 and 1999 are similar in terms of passengers, operations, and environmental impacts, this Supplemental DEIS/FEIR includes the 1998 modeling analysis as representative of recent conditions at Logan.

16 *Logan Airport 1998 Annual Update*, October 15, 1999
17 *Logan Airport 1999 Environmental Status and Planning Report*, December 15, 2000.
18 A more detailed comparison of the change between 1998 and 1999 passengers and operations is included in Chapter 2 of the ESPR.
19 A more detailed comparison of the change between 1998 and 1999 noise impacts is included in Chapter 6 of the ESPR.
20 The ESPR compares all of the 1998 and 1999 analyses and discusses the differences in detail.

Table 1.3-1
Air Passengers, Aircraft Operations, and Freight: 1980 to 2000

Year	Air Passengers (000)	Annual Percent Change	Flight Operations (000)	Annual Percent Change	Total Cargo and Mail* (000 lbs.)	Annual Percent Change

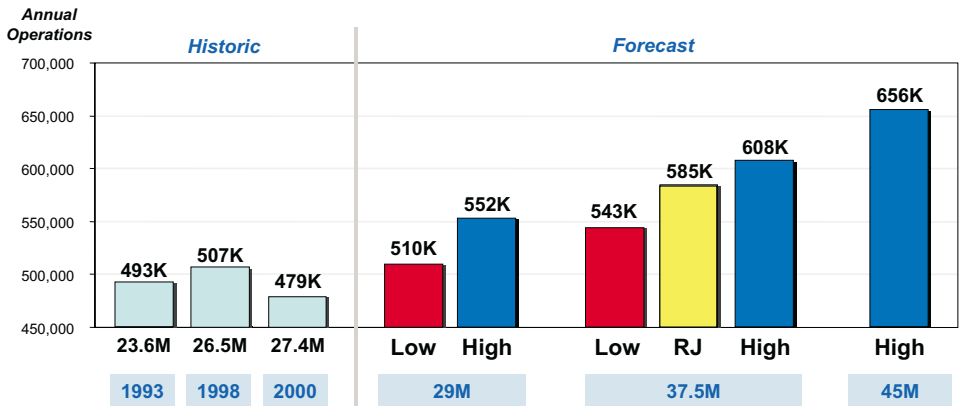
1.3.2 Forecast Aircraft Operations and Passenger Levels

Airline passenger traffic, both locally and nationally, has increased dramatically over time and is forecast to continue to grow into the future. The airfield operational and environmental impact analyses presented in the Airside Project Draft EIS/EIR and this Supplemental DEIS/FEIR are based on forecasts of future aircraft operations and passenger demand for Logan Airport. Multiple aircraft fleets were analyzed for each future passenger demand level. An aircraft fleet consists of a mix of different aircraft types (i.e., large jets, regional jets and non-jets). A fleet with a high proportion of large jets, which carry more passengers than regional jets or non-jets, requires comparatively fewer annual aircraft operations for a given number of passengers than a fleet with a lower proportion of large jets.

Massport has adopted a range of near-term and long-term activity forecasts for planning purposes (see Figure 1.3-1). Annual passenger demand for Logan Airport is forecast to reach 29 million passengers (29M) early in this decade. Logan's most recent annual passenger level is 27.4 million for 2000, or 96 percent of the 29 M near-term passenger forecast.[21] If Logan remains on its current growth path, which due to the effectiveness of regional planning efforts is slower than its historic long-term growth trend, the Airport is expected to reach 29 million passengers in 2003, 34 million passengers by 2010, and 37.5 million passengers (37.5M) in 2015. These projections are more conservative than the forecasts presented in the Airside Project Draft EIS/EIR, which assumed that Logan would reach these activity levels earlier, i.e., 29M in 1999 and 37.5M in 2010. Nevertheless, the analyses presented in the Airside Project Draft EIS/EIR remain valid because they present the operational and environmental impacts associated with a range of future near-term and long-term operating levels. The revised forecast dates are consistent with the FAA's most recent Terminal Area Forecasts for Logan Airport. In its 1999 Terminal Area Forecasts, the FAA projects that Logan Airport will reach 33.6 million passengers in 2010 and 37.1 million passengers in 2015.

Figure 1.3-1
Logan Airside Passenger and Fleet Forecasts – Annual Operations by Fleet



21 Massport's planning forecasts were reviewed in the *Logan Airport 1999 Environmental Status and Planning Report*, December 15, 2000.

Massport's projected operations for the near-term (i.e., 29 million passengers) are 510,000 for a Low Fleet scenario and 552,000 for a High Fleet scenario. For the long-term (i.e., 37.5M passengers), annual aircraft operations are forecast to range from 543,000 to 608,000. The forecast range for aircraft operations reflects different assumptions regarding the aircraft fleet mix at Logan. The Low Fleet scenarios assume only two major regional airlines and a higher proportion of large jet aircraft operations than assumed in the High Fleet scenarios. The High Fleet scenarios assume a fleet mix similar to 1993 conditions, when three major regional carriers operating non-jet aircraft accounted for nearly 50 percent of total airport operations and airline overscheduling occurred during peak periods. For this Supplemental DEIS/FEIR, an alternative future fleet, which is characterized by a high proportion of the new technology regional jets, was evaluated for the 37.5M passenger level.

The analysis in this Supplemental DEIS/FEIR focuses on a comparison between the Preferred Alternative (Alternative 1A) and the No Action Alternative (Alternative 4) for the 29M Low Fleet and the 37.5M High Fleet scenarios, which were previously analyzed in the Airside Project Draft EIS/EIR. The operational and environmental analyses for Alternatives 1, 2 and 3 for the 29M Low Fleet and 37.5M High Fleet are summarized in Appendices E and F. All alternatives for the new 37.5M High RJ fleet are analyzed in this Supplemental DEIS/FEIR. For ease of reference, the analysis assumptions used in this Supplemental DEIS/FEIR are summarized in Table 1.3-2. The alternative fleet scenarios are more fully described in Chapter 4 of this report.

Table 1.3-2
Passenger and Aircraft Operations Analysis Assumptions

Time Frame	Annual Passengers	Annual Aircraft Operations	Fleet Assumptions	SDEIS/FEIR Alternatives	SDEIS/FEIR Airside Scenarios
Near Term	29 million	510,000	Low Fleet ■ 2 major regional carriers ■ No airline overscheduling	1A and 4 [1]	29M Low Fleet
Long Term	37.5 million	608,000	High Fleet ■ 3 major regional carriers ■ Airline over scheduling during peak periods	1A and 4 [1]	37.5M High Fleet
Long Term	37.5 million	585,000	High RJ Fleet ■ 3 major regional carriers ■ Regional jet aircraft 31% of the fleet ■ Airline overscheduling during peak periods	1, 1A, 2, 3 and 4	37.5M High RJ Fleet

1 Analysis results for Alternatives 1, 2 and 3 are contained in Appendices C, E and F. Analysis results for other fleet scenarios are contained in the Airside Project Draft EIS/EIR.

1.3.3 Logan's Demand Profile

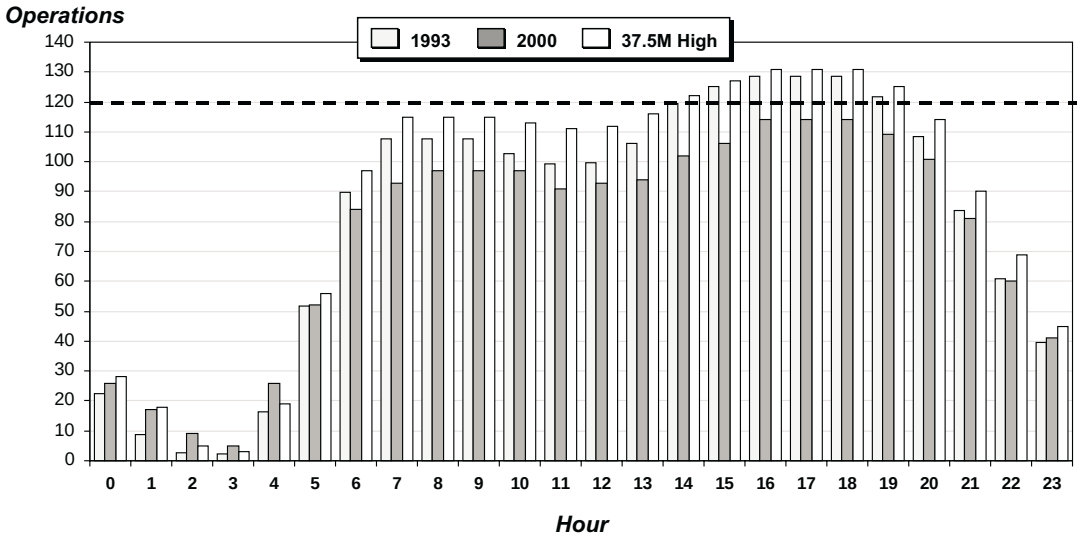
While the volume of annual operations is critical for evaluating Logan's operational and environmental impacts, the distribution of that volume is also important. Flight demand varies by hour, by day of week, and by season, and this variation can have a significant impact on airport delays. This pattern of hourly flight activity is referred to as the airport demand profile.

Logan's capacity during visual flight rules (VFR) conditions is approximately 120 operations per hour, and these VFR conditions prevail approximately 80 percent of the year. Under these good weather conditions, delays accumulate only when demand exceeds the VFR capacity of the airport for a sustained period of time. If demand at an airport causes delays even in good weather, an overscheduling situation exists.

Delays due to airline overscheduling become significant when flight activity levels exceed airfield capacity for a sustained period of time. When a short period of excessive demand is followed by a period of low activity, the airfield has an opportunity to recover and only moderate delays are incurred. If, however, flight activity levels reach or exceed available capacity for a number of consecutive hours, delays build rapidly as flights delayed during one hour add to schedule demand during the next hour. For this reason, three-hour averages of forecast flight activity levels were used to determine the periods when sustained airline overscheduling conditions exist. It is during these periods that a peak surcharge might be applied.

Figure 1.3-2 compares the August weekday demand profiles for 1993 and 2000 with the forecast demand profile for the 37.5M High Fleet. In 1993, a record year for delays at Logan, demand was considerably more peaked than it is today and exceeded the airport's average VFR capacity of 120 hourly operations and the average all-weather capacity of 115 for six consecutive afternoon hours. In contrast, the August 2000 weekday profile never exceeds the average all-weather capacity. The profile comparison clearly demonstrates that while overscheduling was a problem in 1993, it is not a problem today. The 37.5M High fleet assumes three major regional carriers and a high percentage of non-jet activity. Under this forecast scenario, flight demand exceeds Logan's average VFR capacity for six consecutive hours and the average all-weather capacity for most of the day. Clearly, airline overscheduling can be expected to cause serious delays under these conditions.

Figure 1.3-2
Logan's Average Maximum Three Hour Demand Profile –
1993 vs. 2000 vs. 37.5M High (3 Hour Maximum Average)



1.4 Delays at Logan

Delay simulation modeling conducted for the Airside Project Draft EIS/EIR indicates that Logan experienced approximately 120,000 hours of runway delays in 1998. This is six times the FAA's threshold of 20,000 annual delay hours for identifying severely congested airports, which emphasizes the magnitude of Logan's delay problem.

All available measures of delay confirm the severity of aircraft delays at Logan. For 2000, the FAA reports that Logan ranked 6th among the nation's largest airports in delayed operations and 2nd in arrival delays, yet it was only the 12th, busiest US airport in terms of aircraft operations.

This section presents historical delay statistics for Logan and comparative delay measures for Logan and other major US airports. The section also provides a description of existing delay measures, identifies the inherent drawbacks of these statistics, and discusses the appropriateness of simulation modeling for estimating delays. The various delay databases maintained by the FAA and US DOT, and the methodologies employed by each to quantify delays are described in Appendix C of this Supplemental DEIS/FEIR.

1.4.1 Delays at Logan and Other US Airports

This section presents delay statistics and rankings for Logan from a variety of sources, including the FAA, the US DOT and simulation modeling performed by both the FAA and the Airside Project study team. While varying methodologies produce different rankings and estimates of delay, these sources are consistent in demonstrating a serious delay problem at Logan. Table 1.4-1 presents Logan's rank since 1990 among US airports by total delayed operations from the FAA Air Traffic Operations Network (OPSNET).[22] Based on this delay measure, the FAA has consistently designated Logan as a "seriously congested airport." The table also shows that Logan's rank by arrival delays has progressively worsened over the past decade. For the most recent year, Logan ranked second nationwide—its worst ranking since at least 1990.

Table 1.4-1
Logan's Airside Delay Rank Among US Airports

Year	Rank by Total Delays	Rank by Arrival Delays
1990	9	9
1991	6	7
1992	6	6
1993	5	6
1994	6	4
1995	9	4
1996	9	4
1997	9	3
1998	6	3
1999	7	5
2000	6	2

Source: FAA Air Traffic Operations Network (OPSNET)

Table 1.4-2 compares operations and delays at ten of the busiest airports in the United States based on the FAA OPSNET data. In 2000, New York LaGuardia had the nation's worst delay problem according to OPSNET, followed by Newark and Chicago O'Hare. While Logan ranked 5th in delays per 1,000 operations (and 6th in total delays), it experienced a significantly higher rate of delay than Atlanta, Dallas/Ft. Worth, and Los Angeles even though these airports accommodated 54 to 80 percent more operations than Logan.

22 OPSNET is the official FAA delay reporting system for air traffic management purposes and was formerly known as the Air Traffic Operations Management System (ATOMS). Additional information is provided in Appendix C of this Supplemental DEIS/FEIR. OPSNET counts only the number of flights that suffer a delay of more than fifteen minutes at a single element of the air traffic control (ATC) system (a sector or airport).

Table 1.4-2
FAA OPSNET: 2000 Delay Ranking for Ten of the Busiest US Airports

Airport	Operations	Delayed Flights	Delayed Flights per 1,000	Delayed Arrivals	Delayed Arrivals per 1,000
Atlanta	913,449	28,229	30.9	11,022	24.1
Boston Logan	**508,283**	**24,120**	**47.5**	**6,863**	**27.0**
Chicago O'Hare	908,977	57,545	63.3	4,801	10.6
Dallas/Ft. Worth	865,777	20,638	23.8	1,180	2.7
Los Angeles	783,684	17,141	21.9	1,142	2.9
New York Kennedy	358,951	13,930	38.8	648	3.6
New York LaGuardia	392,047	61,120	155.9	3,856	19.7
Newark	457,182	37,132	81.2	3,836	16.8
San Francisco	430,612	24,478	56.8	6,541	30.4
St. Louis	484,224	8,837	18.2	1,178	4.9
	Comparative Operations Index*	**Rank**	**Rank**	**Rank**	**Rank**
Atlanta	180	4	7	1	3
Boston Logan	**100**	**6**	**5**	**2**	**2**
Chicago O'Hare	179	2	3	4	6
Dallas/Ft. Worth	170	7	8	7	10
Los Angeles	154	8	9	9	9
New York Kennedy	71	9	6	10	8
New York LaGuardia	77	1	1	5	4
Newark	90	3	2	6	5
San Francisco	85	5	4	3	1
St. Louis	95	10	10	8	7

Note: Boston ranks 5th in operations among the airports listed, but 12th nationally. Other delay rankings for Logan are also national delay rankings.

* Operations Index-- Boston = 100

Source: FAA Air Traffic Operations Network (OPSNET)

Table 1.4-3 compares 2000 delay estimates from the US DOT's Air Traffic Consumer Reports (ATCR)[23] for the same ten busy US airports. This table shows the percentage of arrivals or departures that were delayed by more than 15 minutes at each airport. While arrivals are delayed more frequently than departures at most airports, Logan has the fourth highest percentage of arrival delays based on the ATCR data. This is similar to the OPSNET data that showed Logan with the 2nd highest rate of arrival delays. The two rankings differ because of different methodologies for counting delays. For example, ATCR estimates that 35 out of 100 arrivals were delayed at Logan in 2000, but OPSNET counts 3 arrival delays per 100 flights. While the methodologies for counting delays differ, both databases indicate that Logan experiences a higher rate of arrival delays than nearly all other large US airports.

Table 1.4-3
US DOT Air Travel Consumer Report: Percentage of Flights Delayed by 15 Minutes or More at Ten Busy US Airports in 2000

Airport	Departure Flight Delays	Arrival Flight Delays
Atlanta	23.4%	25.1%
Boston Logan	**25.3%**	**34.5%**
Dallas/Ft. Worth	21.9%	22.0%
Newark	23.6%	30.8%
New York Kennedy	20.7%	28.1%
Los Angeles	27.8%	33.5%
New York LaGuardia	28.9%	42.9%
Chicago O'Hare	33.2%	36.8%
San Francisco	30.0%	39.2%
St. Louis	22.9%	22.4%

Source: US DOT, Air Travel Consumer Report.

Table 1.4-4 ranks the 29 Large Hub[24] US airports by average minutes of delay by phase of flight based on the FAA's Consolidated Operations and Delay Analysis System (CODAS)[25] data for 12 months ending November 2000. Boston is ranked 5th worst by airborne delays, 3rd by arrival delays, 7th in taxi-in delays and 10th by taxi-out and gate delays. The CODAS data captured 81 percent Logan's actual 2000 operations. The arrival delay ranking is comparable with the OPSNET and ATCR databases.

23 The US DOT's Air Traffic Consumer Reports (ATCR) provide information about the on-time performance of airline flights. They are based on Airline Service Quality Performance (ASQP) data filed by major carriers. See Appendix C for a full discussion of public delay databases.

24 Large Hub airports are those airports enplaning one percent or more of total passengers. There are 29 Large Hub airports in the US.

25 CODAS was created by the FAA, Office of Policy and Planning to provide more consistent estimates of aircraft delay by combining data from several existing sources, including data from the FAA, US DOT, the Official Airline Guide (OAG), the air carrriers' Computerized Reservation System (CRS) and the Air Transport Association (ATA). See Appendix C for a full discussion of public delay databases.

Table 1.4-4
FAA CODAS: Average Delay by Phase of Flight at the 29 Large Hub Airports (Minutes) – 12 Months Ending November 2000

1.4.1.1 Comparison of Simulated Delays and Measured Delays

Many reviewers of the Airside Project Draft EIS/EIR have inappropriately compared the Airside modeled delays with the FAA and US DOT delay reporting databases and suggested that Massport's analysis overstates delays at Logan. These measures are not directly comparable. Delay simulation models estimate total annual hours of delay, and are more comprehensive than the FAA and US DOT delay reporting systems, which only report a portion of actual delays incurred. Table 1.4-5 shows the differences between modeled delays and delays reported in the OPSNET and ATCR databases for Logan Airport. As shown, the simulated results for flights delayed over 15 minutes in 1993 and 1998 actually fall between the values reported by the FAA and the US DOT.

The differences between the modeled and reported delays reflect the limitations of the OPSNET and ATCR delay reporting systems, and the fact that FAA and US DOT delay accounting systems serve different purposes than simulation modeling. (These differences are discussed in Section 1.6.2 of the Airside Project Draft EIS/EIR and in Appendix C of the Supplemental DEIS/FEIR.) Recognizing these differences, the FAA uses delay simulation models to assess the benefits of major airport investment projects such as new runways.

Table 1.4-5
Comparison of Airside Modeled Delays and FAA/DOT Reported Delays for Logan Airport

Delay Source	Measure	1993	1998
Airside Analysis	**Operating Delays > 15 min**	**13.6%**	**14.0%**
FAA OPSNET	Operating Delays > 15 min	3.9%	3.2%
US DOT ATCR	Arrival Delays > 15 min	26.6%	28.6%
US DOT ATCR	Departure Delays > 15 min	19.2%	19.2%
Airside Analysis	**Average Delay (min)**	**15.6**	**14.0**
FAA CODAS	Average Delay (min)	NA	6.2

1.4.1.2 Comparison of FAA and Airside Simulated Delays for Logan Airport

In 1992, the FAA Technical Center simulated Logan airfield operations with the Runway Delay Simulation Model (RDSIM) model and estimated that total delay would approach 270,000 hours per year at an activity level of 504,000 annual operations.[26] In comparison, simulation modeling for the Logan Airside Improvements Planning Project estimated 120,000 runway delay hours for an annual operations level of 507,000 in 1998. Table 1.4-6 compares the FAA Technical Center modeled delay with the Airside Project's delay estimate. As shown, the Airside Project's results are lower than what the FAA model predicted at a similar level of operations. The FAA has concluded that the Airside Project modeled delays represent "a plausible and conservative estimate when compared with the earlier and simpler Logan Capacity Task Force simulation of the Airport."[27]

1.4.2 Delays at Other Airports and Changes in Logan's Delay Ranking

During the meetings of the SDEIS Panel, a number of questions were raised about the delay modeling in the Airside Project and the interpretation of the simulation results. The modeling results presented throughout the Draft EIS/EIR and this Supplemental DEIS/FEIR represent only those delays that are attributed to Logan conditions. While these Logan-caused delays are clearly the most appropriate measures for evaluating the airside improvements, the FAA and Massport decided to also assess these delays within the greater context of the total delays at Logan. In addition to delays due to Logan congestion, delays can also accrue due to congestion elsewhere in the national air transportation system. For example, congestion at LaGuardia frequently results in gate holds for passengers departing from Logan; however, since these are not Logan-caused delays, they are not reflected in the modeling results for this project. It is therefore important to understand not only the impacts of the potential airside improvements on the Logan-caused runway and taxiway delays, but also on total delays, including those caused by other airports. This requires a basic understanding of how runway and taxiway delays relate to total Logan delays, how delays at other airports affect Logan, and how congestion at Logan impacts other airports. Within this context, the FAA and Massport assessed how Logan's national delay ranking might change if the proposed airside improvements were implemented.

Section 1.6.2 of the Airside Project Draft EIS/EIR and Appendix C of this Supplemental DEIS/FEIR describe the strengths and limitations of the FAA Consolidated Operations and Delay Analysis System (CODAS), which is generally considered to be the most comprehensive database of delay statistics available. While these delay statistics are not directly comparable to the simulation results, they do contain causal information that can be used to better assess the overall delay picture at Logan. CODAS statistics include delays for all phases of flight (gate, taxi-out, airborne, and taxi-in), but the gate delays are further segregated into Estimated Departure Clearance Time (EDCT) "Where Taken" and "Where Caused" delay. For example, a twenty-minute gate hold at LaGuardia due to northwest wind congestion at Logan would be counted as twenty minutes of "Where Taken" delay for LaGuardia and twenty minutes of "Where Caused" delay at Logan. These statistics are the only benchmarks that capture the impact that a disruption at one airport can have on the ability of another airport to operate on schedule. For that reason,

these measures are the most appropriate for assessing the impact of Logan on other airports and the impacts of those other airports on Logan.

Table 1.4-7 presents CODAS delay statistics for Logan and for the top ten Large Hub destinations served from the airport.[28] For the twelve months ending November 2000, Logan was fifth in terms of total delay and third in terms of arrival delay.[29] While these statistics emphasize the delay problems faced at the airport and the need for the proposed airside improvements, the EDCT "Where Taken" and "Where Caused" delays further explain the interaction between Logan delays and delays at other airports. Figure 1.4-1 shows the flight frequencies between Logan and its top ten Large Hub destinations.

Table 1.4-7
CODAS Delays for Logan and Its Top Ten Large Hub Destinations

Airport	Pct of Logan Sched Deps	Total Delay Mins/Op	Total Delay Rank	Arrival Delay Mins/Op	Arrival Delay Rank	"Where Taken" Delay Mins/Op	"Where Taken" Delay Rank	"Where Caused" Delay Mins/Op	"Where Caused" Delay Rank

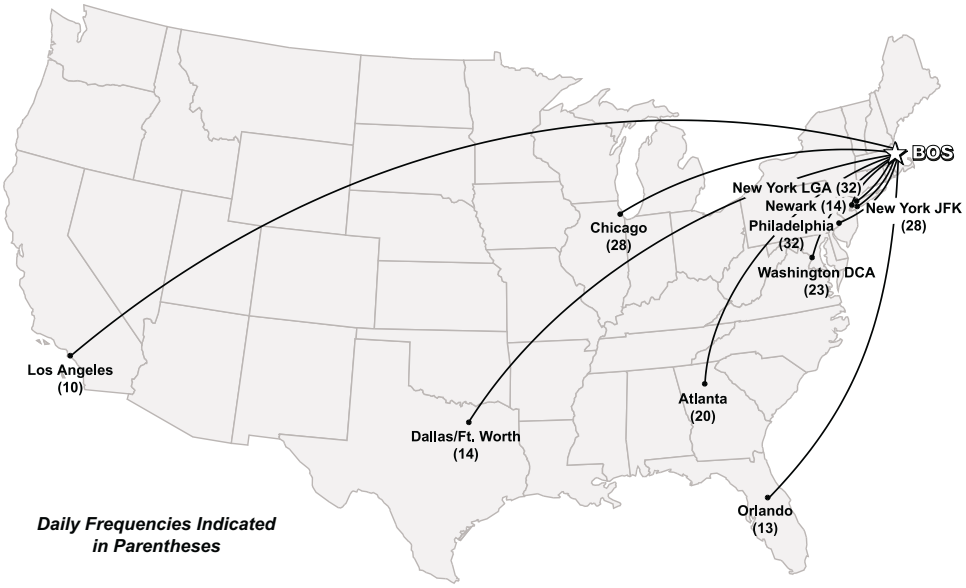
Delays from FAA APO CODAS for 12 months ending Novermber 2000.
Rank indicates rank among the 29 US Large Hub airports.

28 Large Hub airports are those airports enplaning one percent or more of total passengers. There are 29 Large Hub airports in the US.
29 Note that these rankings are the rankings relative to the 29 Large Hub airports in the US.

Figure 1.4-1
Logan Top 10 Large Hub Destinations



Logan ranks fifth in "Where Caused" delay, indicating that Logan is one of the airports most likely to cause delays at other airports and departure gate holds in particular. Airports ranked above Logan in "Where Caused" delay include LaGuardia, O'Hare, and Newark, three of the most delayed airports in the US. LaGuardia and O'Hare are both known for causing major delays throughout the air traffic network, and both O'Hare and Newark are hub airports with banks of flights that influence airports throughout the country. The fact that Logan ranks close behind them in "Where Caused" delays indicates that Logan congestion is having a major impact throughout the national air transportation system.

Logan also experiences a significant number of delays due to congestion at other airports, as evidenced by its rank of seventh in "Where Taken" delay. In fact, Logan's top destination, LaGuardia, is not only the most delayed airport in the country in terms of total delays and arrival delays, it is also the airport most likely to cause delays at other airports. Since LaGuardia is Logan's top destination, Logan experiences a large number of gate hold delays due to LaGuardia congestion. Similarly, major Logan destinations such as Philadelphia, Chicago, Atlanta, and Newark are also among the top ten Large Hub airports in terms of "Where Caused" delay, creating additional Logan delays that have nothing to do with Logan congestion.

While the "Where Caused" delay statistic represents only a sub-set of the total delays experienced at an airport, it removes the influence of other airports, allowing direct comparison of the delays caused by individual airports. This makes it useful for estimating the total Logan delays caused by other airports relative to the Logan-caused

runway and taxiway delays generated by the simulation models and reported throughout this Supplemental DEIS/FEIR.

While Table 1.4-8 presents only the top ten airports in terms of the delay they cause at Logan, the calculations shown were performed for each Logan destination. First, the "Where Caused" delays for each airport were compiled and compared to Logan's "Where Caused" delay value of 2.75 minutes per arrival (see Table 1.4-7). Next, the most recent simulated runway and taxiway delay hours were distributed among the airports served directly from Logan. The 142,000 hours of annual runway and taxiway delay developed for the updated 1998 baseline analysis were assumed to represent current delays and were distributed according to the percentage of Logan departures to each destination airport. For example, LaGuardia represents 5.1 percent of Logan's scheduled departures, it was therefore assumed that 5.1 percent of Logan's 142,000 modeled runway and taxiway delay hours (approximately 7,200 hours) were accumulated by operations serving LaGuardia.

After distributing these Logan-caused runway and taxiway delays, it was then assumed that the impact of any airport on Logan is proportional to the ratio of the "Where Caused" delays of the two airports. Using the LaGuardia example once again, since LaGuardia had nearly three times the "Where Caused" delay as Logan, it was assumed that for each hour of Logan-caused delay estimated by the models, Logan passengers also experienced nearly three times as many hours of delay due to LaGuardia congestion. Accumulating these statistics for each airport served directly from Logan, it is estimated that in addition to the 142,000 hours of Logan-caused delay, passengers at the airport currently experience an additional 55,000 hours of delay caused by congestion at other airports.

Table 1.4-8
Estimated Logan Delays Caused by Other Airports

Airport	Pct of Logan Sched Deps	"Where Caused" Delay per Arrival	Delays at Dest as pct of Logan Delays	Est Annual Delay Caused by Logan	Est Annual Delay Caused by Dest
New York LGA	5.1%	8.08	294.4%	7,191	21,170

Total	100.0%	1.06	38.5%	142,000	54,683

Notes:
When no CODAS delays available, 0.01 for US/Canada/Mexico/Caribbean destinations, 2.75 for European/Pacific destinations
Top ten airports ranked by "Est. Annual Delay Caused by Dest."
CODAS delays for 12 months ending November 2000

The analysis shows that the majority of Logan's delays are due to runway and taxiway congestion at the airport, but that the role of other airports should not be ignored. In fact, the analysis demonstrates that delays at other airports make up nearly thirty percent of the total capacity-related delays experienced by Logan passengers. It is also notable that over ninety percent of these delays caused by other airports are due to only ten airports, most of which have "Where Caused" delays similar to Logan's. This implies not only that delay reductions at these airports would benefit Logan passengers, but also that improvements at Logan would benefit passengers at other airports throughout the country.

Based on the analysis of delays at other airports, it is possible to estimate the potential change in Logan's national delay rankings with implementation of the Preferred Alternative. The simulation analysis of 1998 conditions presented in Section 4.6.1 of this Supplemental DEIS/FEIR shows that implementation of the Preferred Alternative would reduce the Logan-caused runway delays by 38,000 annual hours or 32 percent. While taxiway modeling was not performed for the 1998 analysis, based on the results of the 29M Low Fleet analysis, it was projected that the 22,000 estimated baseline taxiway delay hours would be reduced by approximately 15,000 hours under the Preferred Alternative. Based on this delay reduction and the previous analysis of delays caused by other airports, the proposed airside improvements would have reduced total delays at Logan, including those caused by other airports, by approximately 27 percent.

To convert this change in total delays into an estimate of the change in Logan's delay ranking with the Preferred Alternative, assumptions must be made regarding the change in delays at other airports. As demand levels increase, delays at other airports will tend to rise. However, flight delays are a nationwide problem, and there are numerous initiatives underway to address delays at airports throughout the country. These initiatives will tend to reduce delays, but without specific details, it is difficult to estimate the magnitude of the potential delay reductions that may result. For the purposes of this analysis, it has been assumed that delays at other airports remain constant relative to Logan delays. However, it is important to understand that improvements at other airports will benefit Logan passengers, even if Logan's delay ranking might be negatively impacted as delays at other airports improve.

Logan-caused runway and taxiway delays represent the largest portion of delays experienced at the airport, but Logan is also impacted by delays at other airports, just as those airports are impacted by Logan. This relationship means that improvements at Logan have benefits around the country and that delay reductions at other airports provide benefits to Logan passengers.

Table 1.4-9 shows how Logan's current CODAS delay rankings might have changed with the proposed airside improvements. Logan's national delay ranking would have improved from third to thirteenth in terms of arrival delays and from fifth to fourteenth in terms of total delays if the Preferred Alternative, including Runway 14/32 had been in place. In addition, Logan's arrival delay would be reduced by 5.2 minutes per operation. If other airports made improvements similar to those proposed at Logan (reducing delays by

nearly thirty percent), Logan's delay rankings would be unchanged from the current rankings, but Logan passengers would experience an even greater reduction in delays.

Notes:
Delays from FAA APO CODAS for 12 months ending Novermber 2000.

Overall, this analysis of the interdependencies between airport delays leads to a number of conclusions:

- Logan-caused runway and taxiway delays are the most appropriate measure for evaluating the relative benefits of the proposed Airside Project improvements. While these delays represent the largest portion of Logan delays, Logan is also impacted by delays at other airports.
- Logan-caused runway and taxiway delays account for approximately 70 percent of total capacity-related delays for Logan flights; but the significant proportion of delays caused by other airports indicates a strong relationship between Logan delays and delays at other airports in the national air transportation system.
- This relationship means that improvements at Logan have benefits for air transportation as a whole, and that delay reduction initiatives at other airports will provide benefits to Logan passengers.
- The Preferred Alternative provides a significant benefit, and would have improved Logan's national CODAS delay rankings from third to thirteenth in terms of arrival delays, and from fifth to fourteenth in terms of total delays, assuming no improvements at other airports.

1.4.3 FAA Measures to Reduce Delays Nation-wide.

FAA efforts to improve safety, to reduce congestion and delays, and to accommodate a growing volume of air traffic within the national airspace system are continuing on several fronts: airport development, airspace design, air traffic operational procedures and system modernization.[30]

Improving airport infrastructure is the most direct and effective means of reducing delays. FAA efforts in this area include studies of airport delays and potential improvements, review of airport proprietary improvement initiatives at existing airports, funding airport development through the Airport Improvement Program (AIP) and Passenger Facility Charges (PFCs), development of new airports, and conversion of military airfields to civil use.

National Airspace Redesign (NAR) is an ongoing FAA activity to reduce delays by providing more efficient handling of current and future aircraft flows. The NAR Program is addressing existing chokepoints as well as introducing enroute alternatives. Other efforts involve consolidating Terminal Radar Approach facilities for more efficient control, and developing Area Navigation Routes which are not constrained by fixed ground-based navigational facilities.

Improved operational procedures are being developed and implemented to maximize the capacity of existing or planned airports and airspace. Some specific items in process are

▼

30 *2000 Aviation Capacity Enhancement (ACE) Plan*, FAA Office of System Capacity, December 2000.

reducing the required vertical or horizontal separations between aircraft, increasing civilian access to military special use airspace, implementing GPS approaches, removing the 250-knot airspeed limit below 10,000 feet, Simultaneous Offset Instrument Approaches (SOIA) to closely spaced parallel runways, and greater use of Land and Hold Short Operations (LAHSO).

To handle the growing demand on the air traffic system and associated delays, the FAA has prepared a long-term plan for National Airspace System (NAS) Modernization. The concept of Free Flight is the impetus for many of the elements of NAS Modernization. Free Flight will give pilots more flexibility in determining routes and speeds. Future NAS users will face fewer enroute restrictions—and thereby fewer delays—in their flight operations. The NAS Modernization Plan contains many interrelated projects, which are described in detail as "NAS Architecture".[31] The Plan includes a combination of hardware, software, new technology, procedural innovations, and collaborative decision-making that will increase system efficiency and reduce delays.

1.5 Logan's Role in the Regional Economy

Efficient aviation facilities are a critical component of a region's economic system and structure. As the largest airport in the six-state New England region, Logan provides air passenger and cargo services to international and domestic destinations, which play a significant role in the Boston and New England economies. This section discusses the importance of convenient air service to the local and regional economies, as well as the effects of Logan as an economic entity that provides employment and other direct and indirect benefits to the economy.

1.5.1 Boston's Need for Efficient Air Travel

The New England economy is largely based on a mix of travel-intensive service industries that depend on high-quality air transportation services. As illustrated in Table 1.5-1, the economies of Boston and the Commonwealth of Massachusetts have higher proportions of employment in the services and finance, insurance, and real estate sectors, than the nation as a whole. Section 1.2.1 of the Airside Project Draft EIS/EIR provides a more detailed description of the service industry in the region, including the number and names of major employers.

▼

31 The complete NAS Architecture 4.0 and a summary called the Blueprint for NAS Modernization are posted on the FAA web site at www.faa.gov/nasarchitecture.

Table 1.5-1
Share of Employees by Industry Sector

Industry Sector	Boston	MA	US
Services	40%	36%	30%
Wholesale and Retail Trade	22%	23%	23%
Manufacturing	11%	14%	15%
Government	11%	12%	15%
Finance, Insurance, Real Estate	8%	7%	6%
Construction and Mining	3%	4%	5%
Transportation, Communications and Utilities	4%	4%	5%

Source: US Department of Labor, Bureau of Labor Statistics, Employment and Earnings, September 1998.

The major service industries in the region include financial services, research and development, higher education, consulting, high technology, and health care and medical services. All of these industries are travel intensive because they operate in national and global markets with clients around the world. These industries often involve collaborative efforts among individuals or corporations that work closely together despite distances. Boston's hospitals and medical services are internationally recognized and highly rated, and therefore draw patients from around the world. As a global center for these industries, the region also hosts related conferences and conventions. Similar large gatherings from many other industries are drawn by the region's historic, cultural and natural attractions.

1.5.2 Tourism and the Regional Economy

Tourism is a key sector of the local and regional economies, and tourists that arrive by air typically spend more, stay longer, and provide more economic benefits to the region than those arriving by other modes. In Massachusetts, approximately 108,000 full-time jobs are created by the tourism industry, and 30,000 of these are located in Boston.[32] The number of visitors to the Greater Boston area has increased by 5 percent annually between 1992 and 1997, rising from 8.8 million to 11.1 million.[33] Visitors come from all over the US and the world. Over half of Boston's US visitors come from outside New England and more than one-fourth arrive by air. More than a million international visitors (excluding residents of Canada and Mexico) come to Boston annually, each spending an average of $1,400 during their stay.[34]

1.5.3 Logan is a Major Employer and Economic Catalyst

In addition to supporting the intercity travel needs of the region's businesses and facilitating the tourism trade, Logan itself is a major contributor to the regional economy. Activity at Logan generated an estimated $1.4 billion in direct economic benefits and

32 *1997 Fact Sheet,* Greater Boston Convention and Visitors Bureau
33 *1998 Fact Sheet*, Greater Boston Convention and Visitors Bureau
34 *1997 and 1998 Fact Sheets*, Greater Boston Convention and Visitors Bureau

$5.0 billion, or an average of $13.6 million every day, in total economic benefits during Fiscal Year 1998 (see Table 1.5-2).[35]

As owner and operator of Logan Airport, Massport provides most of Logan's major facilities, leases land and building space to other businesses at the airport, and coordinates ground access services to Logan. Massport employs more than 700 people at Logan. Massport is also continually planning for the airport's future needs through capital investment programs and is responsible for financing the facilities, as well as raising the necessary capital by leveraging revenue primarily from fees and rentals paid by airport users. Some airport costs are partly offset by federal grant money.

More than 60 airlines serve Logan and some 100 aviation-related businesses provide airport support services. Passenger travel services are augmented by restaurants and retail shops in the terminals; hotels; banks; medical offices; rental car agencies; and limousine, bus and taxi services. Of the 15,000 people working at Logan, only about 5 percent are employed by Massport, with the remaining 95 percent are employed by private industry and other government entities. In addition to the direct economic impacts of these activities at Logan, indirect benefits are generated as the tourist and supplier industries support the air transportation business at Logan. Additional economic activity and jobs, generated by these employees through the "multiplier" effect as they spend their paychecks, are included in the $5.0 billion of total economic benefits generated by Logan each year (see Table 1.5-2).

Table 1.5-2
Estimated Economic Impact of Logan - Fiscal Year 1998

Activity	Amount in $ millions
Direct Economic Benefits:

1.6 Cost of Delay on Logan Users

Delays at Logan impose substantial costs on airlines and passengers. Massport estimates that Logan flight delays cost airlines and passengers more than $300 million in 1998. When flights are delayed, the following types of costs are incurred:

- Airlines experience additional operating costs such as increased fuel, maintenance and crew costs;
- Passengers onboard the aircraft risk missed connections and lose personal or work-related time.

Additional costs, that have not been quantified, accrue to people waiting to meet delayed passengers and to shippers who may miss important flight or delivery times. Additional discussion of the costs of delay was provided in Section 1.6 of the Airside Project Draft EIS/EIR.

1.6.1 Cost of Delay to Airlines

The costs associated with delay are often difficult to quantify and require the use of different metrics. The magnitude of airport user costs can be estimated from data on airline operating costs and from FAA statistics on the value of time. Based on these metrics, the estimated airline cost per hour of delay ranges from $348 for a representative regional carrier non-jet aircraft[36] up to $1,585 for a representative 150-seat jet. Given the mix of aircraft operating at Logan, the average airline cost of delay is estimated at $1,115 per hour.

1.6.2 Cost of Delay to Airline Passengers

When flights are delayed, passengers incur lost time. The average passenger aircraft at Logan enplaned (or deplaned) 53 passengers in 1998.[37] On average, when a Boston aircraft is delayed by a single hour, 53 passengers each lose one hour of time. In a 1997 FAA Office of Aviation Policy and Plans (APO) Bulletin, the US DOT/FAA recommended the use of a $27 per hour value of time[38] for the evaluation of regulatory programs impacting airline passengers. Using this value, the average economic cost to airline passengers for a single hour of aircraft delay is $1,431 per flight.

1.6.3 Total Cost of Delay

Considering the impact of delay on both airline operating costs and lost passenger time, the total cost of delay at Logan is estimated at approximately $2,500 per hour, producing

36 Regional aircraft costs reflect a blend of 19-seat Beech-1900 and 34-seat Saab 340. In 1998, these were the most prevalent regional aircraft at Logan.
37 Massport statistics.
38 US DOT/FAA, "Treatment of Values of Passenger Time in Economic Analysis," *APO Bulletin* (APO-97-1), June 1997.

an annual cost of more than $300 million in 1998.[39] The hourly cost of delay can be applied to the estimated hours of delay reduction that will result from the various Airside Project Alternatives, in order to quantify the benefit associated with each.

1.7 Federal/State Purpose of this Supplemental DEIS/FEIR

This Supplemental DEIS/FEIR, like the Airside Project Draft EIS/EIR, was jointly prepared by the FAA and Massport. Because this Supplemental DEIS/FEIR and the Draft EIS/EIR form parts of the federal record of compliance with the National Environmental Policy Act (NEPA) and related provisions of federal law, both have been prepared under the control and responsibility of the FAA.

Massport is the proponent of all the actions studied in this Supplemental DEIS/FEIR with the exception of the proposed reduction in approach minimums on Runways 22L, 27, 15R, and 33L. FAA is the proponent of the reduced approach minimums. FAA also has primary federal jurisdiction and responsibility with regard to regulatory review and approval of airport layout plans, and airport improvement program grants of financial assistance for such projects. Therefore, FAA is acting as the lead federal agency under NEPA with responsibility for preparing this Supplemental DEIS. The Massachusetts Executive Office of Environmental Affairs, MEPA Office, is the reviewing agency for the Final EIR.

1.7.1 NEPA/MEPA History of the Airside Project

A range of Logan-specific alternatives to reduce congestion and delay and enhance safety and efficiency at Logan have been considered in the Logan Airside Improvements Planning Project (Airside Project). The Project was initiated in 1993 as a feasibility study that examined the nature of delays at Logan and evaluated the potential delay savings and efficiency and safety enhancements for a range of improvement concepts.[40] The concepts evaluated in the Airside Improvements Feasibility Study evolved from alternatives considered in previous studies, most notably the FAA's *Boston Logan International Airport Capacity Enhancement Plan* (CEP) published in October 1992. Additional sources for the concepts included the *Logan Runway Incursion Mitigation Plan/Taxiway Relocation Study* (December 1993) and recommendations by Massport staff, airlines, and the Air Transport Association (ATA).

39 Estimated annual cost is for runway delay only.

40 *Logan Airside Improvements Feasibility Study, Phase I Report*, prepared by Jason M. Cortell Associates, Inc. for the Massachusetts Port Authority, July 20, 1995.

Based on the results of the Airside Improvements Feasibility Study completed in 1995, the Massport Board in July 1995 selected seven improvement concepts for advancement of a more detailed operational and environmental analysis through a joint federal and state EIS/EIR. The seven alternatives were presented in the Environmental Notification Form (ENF) for the Airside Project and further developed during the federal and state EIS/EIR scoping process. Consistent with the federal and state scopes, the Airside Project Draft EIS/EIR assessed the following improvement concepts:

- Construction of a unidirectional Runway 14/32;
- Construction of a Centerfield Taxiway;
- Extension of Taxiway Delta;
- Realignment of Taxiway November;
- Optimization of taxiways in the southwest corner of the airfield;
- Reduction in approach minimums on Runways 22L, 27, 15R, and 33L; and
- Implementation of Peak Period Pricing.

The analytic framework for assessing the various alternatives was structured to provide a comprehensive assessment of improvement concept packages.

Out of the possible alternatives, Alternative 1A emerged as the one best able to satisfy the Airside Project's purpose and need. If available in 1998, Alternative 1A would have reduced delays during northwest wind conditions by nearly 90 percent. Alternative 1A, the Preferred Alternative includes all actions analyzed with the exception of Peak Period Pricing.

The Preferred Alternative reduces delays without unnecessarily imposing the economic costs associated with Peak Period Pricing on regional carriers and small communities. Airline overscheduling is not currently a problem at Logan but could emerge in the future. Massport has designed a Peak Period monitoring system for early identification of airline overscheduling, and will initiate a Peak Period Pricing program if warranted by future conditions.

The Preferred Alternative significantly reduces congestion and delay at Logan particularly during northwest wind conditions; achieves important air quality and noise benefits; and increases the safety and efficiency of airfield operations.

There is no feasible and prudent alternative to the Preferred Alternative that would achieve the purpose and need of the Airside Project. The Preferred Alternative is part of a broader program that includes aggressive development of regional options to relieve Logan and all reasonable steps to minimize adverse effects of airport operations.

On February 1, 1999, Massport and the FAA jointly submitted the Airside Project Draft EIS/EIR that analyzed proposals contained in the Logan Airside Improvements Planning Project. After careful review of the extent and causes of delay at Logan, the Airside Project Draft EIS/EIR evaluated the likely level of delay and the environmental implications if nothing is done. This evaluation was completed using state-of-the-art delay modeling techniques and reflected the range of likely activity levels at Logan over the coming decades and the projected role played by regional airports and rail to divert traffic which would otherwise utilize Logan.

A Notice of Availability of the Airside Project Draft EIS/EIR was published in the *Federal Register* on February 26, 1999 and in the *Environmental Monitor* on February 23, 1999. The state and federal comment periods, which started on the notification dates, ended on April 22 and April 23, 1999, respectively. Public Hearings were held by the FAA on April 7, 1999 at the State Transportation Building in Boston and on April 8, 1999 at the Holiday Inn in East Boston.

On May 7, 1999, the Secretary of Environmental Affairs issued a Certificate on the Airside Project Draft EIR which determined that the Draft EIR adequately and properly complied with the Massachusetts Environmental Policy Act (M.G.L. c. 30, §§ 61 - 62H) and with its implementing regulations (301 C.M.R. 11.00) and provided specific direction for additional analysis to be included in the Final EIR.

In January 2000, after reviewing a draft Final EIS, the FAA requested preparation of a Supplemental Draft EIS to address a series of specific issues. At the FAA's direction, an SDEIS panel was formed consisting of three members appointed by the Governor of the Commonwealth of Massachusetts and three members appointed by the Mayor of the City of Boston. Under the direction of the New England Region FAA, the SDEIS panel convened in March of 2000 and held 12 formal meetings and five informational visits to the regional airports and the Logan air traffic control tower. To provide appropriate background, the SDEIS Panel was presented with an Interim Supplemental Draft EIS; answers to key letters written by members of the public, concerned agencies and public officials responding to the Draft EIS/EIR; and a series of 15 visual and written presentations from the Airside Project's technical consulting team and other independent industry experts. Based on the SDEIS Panel process, the FAA developed specific additional analytic tasks to be included in this Supplemental Draft EIS. (The FAA task directive and minutes from the SDEIS Panel meetings are contained in Appendix A of this Supplemental DEIS/FEIR).

This document includes the additional analysis identified by the FAA as a result of the SDEIS Panel review process and constitutes the Supplemental Draft EIS. This document also responds to the EOEA May 7, 1999 Certificate on the Airside Project Draft EIS/EIR and includes separate volumes containing responses to individual comment letters received on the Airside Project Draft EIS/EIR.

1.7.2 FAA Determinations

1.7.2.1 NEPA Record of Decision

Final FAA NEPA determinations are to be made in the FAA Record of Decision following completion of the EIS process.

1.7.2.2 FAA's Regulatory Determinations

Pursuant to FAA's regulatory responsibilities, this Supplemental Draft EIS sets forth evidence demonstrating that:

(a) The project is reasonably consistent with existing plans of public agencies for development of the area;

(b) Fair consideration has been given to the interests of communities in or near the project location;

(c) Appropriate action has been or will be taken to restrict, to the extent reasonable, the use of land in the vicinity of the airport to purposes compatible with airport operations;

(d) Appropriate air and water quality requirements will be satisfied; and

(e) The action is consistent with the approved state coastal zone management program.

1.7.2.3 FAA's 4(f) Assessment

As set forth in this Supplemental DEIS/FEIR, the Preferred Alternative will not use any publicly owned land from a public park, recreation area, wildlife or waterfowl refuge, or land of an historic site. As a result, a Section 4(f) finding is unnecessary.

1.7.2.4 FAA's Non-Applicability Finding with Respect to Clean Air Act Conformity

There are no adverse air quality impacts associated with the Preferred Alternative. In fact, the Preferred Alternative provides air quality benefits when compared to the No Action Alternative. Under Section 176(c) of the Federal Clean Air Act, 42 U.S.C. § 7506(c)(1), the FAA is prohibited from engaging in, supporting in any way, or providing financial assistance for, licensing or permitting, or approving any activity that does not conform to a state implementation plan (SIP). Massport is seeking various FAA approvals for the Preferred Alternative at Boston-Logan International Airport in Boston and Winthrop, Massachusetts. Massachusetts has developed a SIP to achieve attainment of the National Ambient Air Quality Standard (NAAQS) for ozone and a SIP maintenance plan to maintain the NAAQS for carbon monoxide (CO). The Massachusetts SIP lays out a program of controls which seek to control CO emissions directly, and seeks to reduce ozone by reducing emissions of the ozone precursors volatile organic compounds (VOC) [or non-methane hydrocarbons] and oxides of nitrogen (NOx).

1.7.2.5 ALP Approval

The FAA examines, prior to issuing an airport layout plan (ALP) approval or approving financial assistance, whether the Preferred Alternative conforms to the Massachusetts State Implementation Plan's (SIP's) purpose of controlling CO and ozone precursor emissions. For purposes of Section 176(c), the Preferred Alternative is a non-transportation project, subject to the general conformity regulations, 40 C.F.R. Part 51, Subpart W and 40 C.F.R. Part 93, Subpart B.

The Preferred Alternative would not cause emissions that exceed annual General Conformity threshold levels, nor is it a regionally significant action; therefore the proposed action is presumed to conform to the SIP. By reducing congestion and delay in aircraft operations, the Preferred Alternative is expected to reduce CO and VOC emissions under predicted future conditions.

Since the Preferred Alternative will result in a net reduction of emissions over the No Build alternative for both the 29M Low Fleet and the 37.5 M High Fleet scenarios, the project advances the purposes of the Massachusetts SIP. Because the Preferred Alternative will not cause or contribute to any NAAQS violation in any area, and will not delay timely attainment of any NAAQS or any required emission reductions or other milestones in any area, the FAA finds that the Preferred Alternative conforms with the Massachusetts SIP, with the statutory requirements of 42 U.S.C. § 7401 ands 7506(c)(1), and with the regulatory requirements of 40 C.F.R. Part 51, Subpart W and 40 C.F.R. Part 93, Subpart B.

1.7.2.6 FAA's Determination Regarding Environmental Justice

For the reasons set forth in Section 6.8 of this Supplemental DEIS/FEIR, the FAA concludes that the Preferred Alternative does not have a high and adverse disproportionate impact on populations protected by federal environmental justice policies. FAA has committed to approve and fund under the Airport Improvement Program, sound insulation of all residences falling within the predicted 65 dB Day-Night Sound Levels (DNL) contour for the Preferred Alternative under the 29 M Low Fleet scenario, the worst case scenario in terms of noise exposure levels. This includes all areas within the City of Chelsea that would be newly included in the 65 dB DNL contour with the Preferred Alternative. The FAA commitment will be set forth in the Record of Decision. Massport has committed to sponsor and pay for the state's share of sound insulation costs.

1.8 Conclusion

By every available measure of delay, Logan has a serious delay problem. In 2000, Logan was the 6th most delayed airport in the US based on FAA OPSNET statistics, yet it ranked 12th in terms of total aircraft operations. FAA data indicate that Logan's record for arrivals is even worse, ranking as the 2nd most arrival-delayed airport in the nation.

Logan generally operates on three-runway configurations that can accommodate approximately 120 aircraft operations per hour. Most Logan delays occur when wind or weather conditions require all aircraft arrivals and departures to be accommodated on two or fewer runways, producing a substantial decline in airfield operating capacity. As described in the Airside Project Draft EIS/EIR and the following chapters, the Preferred Alternative includes construction of unidirectional Runway 14/32, which would correct an underlying limitation of the Logan airfield – the lack of a third available runway in the northwest/southeast operating direction—and allow normal operational capacity to be maintained during northwest wind conditions. With construction of Runway 14/32, the Preferred Alternative will address the most preventable cause of serious delays at Logan Airport.

It is clear that growth in the Boston and regional economies will continue to stimulate increasing demand for air transportation services at Logan. The challenge faced by Massport and the FAA is to safely and efficiently accommodate current and future levels of demand in an environmentally responsible manner, given the existing physical and operational constraints at Logan. The Airside Project Draft EIS/EIR explored actions that Massport and the FAA can take to improve operational efficiency and enhance safety at Logan. The individual improvements and alternative packages, including the Preferred Alternative, are discussed in Chapter 3 of this Supplemental DEIS/FEIR.

The following chapter of this Supplemental DEIS/FEIR examines the emerging role that regional airports and high speed rail will play in absorbing an increasing portion of the region's air travel demand, and assesses the impact of these regional options on the need for airside improvements at Logan.

2 Logan's Role in the Regional Transportation System

Key Points

Many comments received on the *Airside Improvements Planning Project Draft Environmental Impact Statement/Environmental Impact Report*[1] (Airside Project Draft EIS/EIR) focused on regional transportation issues and the importance of planning for Boston-Logan International Airport in a regional context. These comments were reiterated by the Federal Aviation Administration (FAA) appointed Supplemental Draft EIS Panel (SDEIS Panel) throughout the nine-month review process. The SDEIS Panel repeatedly voiced the need for ongoing regional planning by all relevant regional transportation agencies. In response to the high level of public interest and concern, this chapter expands upon the regional transportation analysis that was presented in the Airside Project Draft EIS/EIR and reports on the progress of regionalization efforts. Specifically, this chapter describes the impact that regional transportation options are having on Logan Airport, the role that Logan plays in a regional system, and planned initiatives to promote a coordinated regional transportation system.

- For more than a decade, transportation planning studies have recommended a regional transportation strategy for New England that includes an expanded role for the regional airports, high-speed inter-city rail as an alternative to air travel, and physical improvements at Logan Airport.

- The region has made considerable progress towards achieving the vision of these regional transportation studies. Substantial capital investments and marketing initiatives have increased passenger acceptance and use of regional airport options to Logan Airport. The December 2000 launch of Amtrak's Acela service will provide Boston-New York passengers with high-speed rail service, another option to Logan Airport service. These accomplishments will divert considerable air passengers from Logan Airport to other regional airports or travel modes and will reduce the region's reliance on Logan for high-speed, intercity travel.

- Service expansion at T.F. Green/ Providence Airport to the south and Manchester Airport to the north has created regional air travel options in New England. By attracting a substantial level of airline services to short- and medium–haul[2] markets, these airports are not only recapturing passengers generated within their own primary

1 *Airside Improvements Planning Project Draft Environmental Impact Statement/Environmental Impact Report*, Massport, February 1999.
2 Short-haul services are less than 750 miles, medium-haul services are 750 to 1,499 miles, and long-haul services are greater than 1,500 miles.

service areas, but are also absorbing demand from the periphery of Logan Airport's core service area.

- Massport's 1999 Passenger Survey confirms that aggressive service expansion at other regional airports, particularly the Manchester and T.F. Green / Providence Airports, is diverting passengers from the areas outside of Metropolitan Boston away from Logan Airport. The share of Logan air passengers with a trip origin in the geographic area outside Interstate-495 has decreased over time, from 22 percent in 1993, to 14 percent in 1999. Massport estimates that regional airports diverted 2.4 million passengers from Logan in 1999.

- Massport is enhancing the capabilities of Worcester Regional Airport and Hanscom Field to offer more choices to air carriers, general aviation users and the traveling public.

  - Since 1995, Massport has been working with the City of Worcester to market Worcester Regional Airport to air carriers. In January 2000, Massport assumed operating responsibility for this airport, and is committed to developing a critical level of air services. Massport has already been successful in attracting several new services to Worcester. These include Delta Connection service to Atlanta, American Eagle service to New York JFK, and Pan Am service to Orlando Sanford International Airport. These services and continued air service development will enable Worcester Regional Airport to attract a meaningful share of Logan Airport passengers from central Massachusetts and the Metro West suburbs of Boston.

  - Massport is also committed to maintaining Hanscom Field within the regional transportation system. Hanscom will continue to serve primarily as a general aviation reliever for Logan Airport, with regional carriers operating niche-commercial air services.

- Massport is promoting increased utilization of regional airports and high speed rail to accommodate a greater share of the region's inter-city travel demand.

- Convenient ground access to Logan Airport as well as the regional airports will promote an efficient regional transportation network. Several progressive ground access improvement projects at Logan, as well as T.F. Green / Providence, Manchester, and Worcester Regional airports, will likely reduce ground traffic congestion and improve the convenience of regional airports.

- Massport supports the regionalization of New England's transportation network and continues to work with aviation transportation agencies including the FAA, the Massachusetts Aeronautics Commission (MAC), other New England State Aviation Directors, and the regional airports, to ensure the efficient use of the region's transportation infrastructure. Massport, the FAA, and the regional airport directors have agreed to undertake an update of the 1995 New England Regional Airports Air Service Study. This *New England Airports System Study* will evaluate the impact of recent regional airport developments on Logan Airport, identify constraints to regional airport

growth, and highlight strategies for optimizing New England's regional aviation system.

- Every major regional transportation study has recognized that the proposed Airside Project improvements at Logan are critical to the success of an efficient regional transportation system in New England. Logan will continue to function as the region's primary airport, accommodating the core Metropolitan Boston demand and the region's demand for international and domestic long-haul travel. The Airside Project improvements that Massport and the FAA have proposed would rectify an underlying limitation of the Logan airfield that causes excessive delays in northwest wind conditions. While regional airports and rail are essential elements of a balanced and efficient inter-city travel network, they cannot relieve Logan delays that occur in specific weather conditions because of a shortcoming in the airfield geometry.

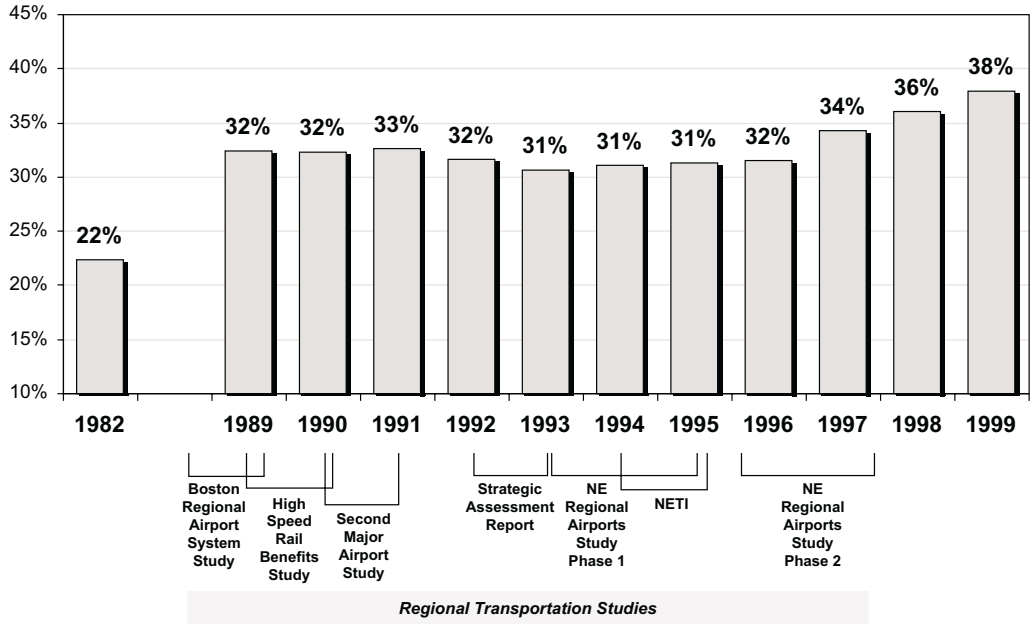
2.1 Overview

Even before the inception of the Airside Improvements Planning Project various concerned citizens and transportation planners have questioned whether increased utilization of other airports and high-speed rail would negate the need for Airside Project improvements at Logan. This question was also raised during the Supplemental DEIS Panel process. Both opponents and proponents of the proposed Logan Airside Project improvements agree that increased utilization of other facilities and modes is a necessary strategy for meeting the growing demand for inter-city travel and maintaining the region's economic success. But, even with high utilization levels, regional airports and high-speed rail would not reduce Logan's demand to levels that would solve Logan's delay problem.

Enhancing the region's transportation infrastructure requires continued development of regional transportation options and investment to improve the efficiency of Logan Airport. The analyses in the Airside Project Draft EIS/EIR and this Supplemental DEIS/FEIR clearly demonstrate that regional airports and improved rail services are not "alternatives" but rather "complements" to the proposed infrastructure improvements at Logan. Regional airports and high-speed rail are part of a balanced and efficient regional transportation system. Developing and promoting these options will slow the growth in future demand for Logan Airport, but will not eliminate Logan's essential role in the regional transportation system.

Transportation planners have long identified the need for other airports and transportation modes to accommodate a greater share of the region's travel demand. Historically, Logan accommodated the majority of the region's demand for high-speed, inter-city travel, accounting for more than three-quarters of the region's air passengers in the early 1980s. Transportation agencies, including Massport, have actively pursued strategies to increase the use of regional transportation options with the goal of reducing the region's reliance on Logan Airport. Through a combination of these efforts and market forces, the regional airports have increased their share of New England's air passengers from 22 percent in the early 1980s to 38 percent in 1999 (Figure 2.1-1).

Figure 2.1-1
Regional Airports' Share of New England Air Passengers



Source: U.S. DOT, Form 41, Part 298/C and airport records.

While regional transportation options increase the efficiency of the overall transportation system, they do not diminish the need for an efficient Logan Airport. Logan plays a critical role in the regional transportation system by serving the Boston market area, which represents the largest concentration of population and commerce in the entire six-state region. As the most populous area in New England, Boston is also the region's largest generator of inter-city trips. In the global economy, high-speed access to distant markets on this continent and beyond is increasingly important to the region's economic success. Since the region's demand is primarily concentrated in the Boston area, Logan is the cornerstone of a regional transportation system and the principal airport for reaching distant long-haul domestic and international markets.

Ongoing efforts to improve regional transportation options are already changing the dynamics of inter-city travel to and from New England. Passenger traffic at the regional airports has increased by 13 percent per year since 1996, while Logan's passenger traffic grew by only 2.5 percent. As efforts to develop regional options have increased, Logan's share of the region's air passengers has declined from 68 percent in 1996 to 62 percent in 1999.

Although more passengers than ever are choosing regional airports and Logan's passenger growth has slowed, flight delays at Logan have not abated. The analysis conducted during this Airside Project EIS/EIR review process as well as all FAA and Department of Transportation (DOT) data, show a consistently high level of flight delays at Logan even as passenger growth has slowed.

While there are several causes of the delays that Logan passengers experience, a principal cause of Logan's delay problem is the inability of the airport to handle normal demand

during strong northwest winds. Proposed unidirectional Runway 14/32 is specifically designed to correct the underlying shortcoming in the airfield layout that causes excessive delays in northwest winds. There is no regional transportation alternative that could address the limitations in Logan's existing runway geometry and eliminate northwest wind delays.

Several regional transportation planning studies have concluded that regional transportation options and physical improvements at Logan are both essential for satisfying New England's transportation need. The region must work to expand transportation options and at the same time improve the efficiency of Logan Airport. This was reiterated by independent transportation experts who participated in the Supplemental DEIS Panel process. A truly regional transportation system cannot function without an efficient Logan Airport and Logan cannot operate efficiently if the source of northwest wind delays is not addressed.

The Airside Project Draft EIS/EIR presented a detailed description of Logan's role within the broader regional transportation network and an analysis of alternatives to Logan Airport that included regional airports, rail and videoconferencing. It was estimated that these alternatives could divert up to 7.3 million air passengers from Logan over the next decade.

The Secretary of the Executive Office of Environmental Affairs (EOEA) May 7, 1999 Certificate on the Airside Project Draft EIS/EIR[3] requested that Massport report on the current status of ground access improvements at the regional airports and their potential impact on future passenger levels; update estimates of passenger diversion to regional alternatives; and summarize the environmental impacts of regional airport expansion. Based upon discussions during the SDEIS Panel process, the FAA also stressed the importance of regional system planning and requested that Massport expand the regionalization analysis by reporting on the planned New England Airports System Study. This study will identify additional regional strategies for reducing Logan delays, by adding historical context to regional planning issues, and by describing the on-going nature of regionalization efforts. This chapter responds to these concerns by:

- Summarizing key points from the Airside Project Draft EIS/EIR
- Describing the regionalization of air transportation in the eastern New England area and presenting an expanded regional transportation analysis
- Discussing the increasing role of the regional airports in accommodating the region's air travel demand and the evolving role for Logan within the regional airport system
- Addressing the roles that T.F. Green/Providence, Manchester, Worcester Regional, Hanscom, and Logan airports can play in the emerging regional aviation system
- Analyzing the potential Logan traffic relief that could be provided by Worcester Regional Airport

3 The Commonwealth of Massachusetts, Executive Office of Environmental Affairs, Certificate of the Secretary of Environmental Affairs on the *Logan Airside Improvements Planning Project Draft Environmental Impact Statement/Environmental Impact Report*, May 7, 1999.

- Summarizing the status of various rail projects and their potential to divert passengers from Logan
- Discussing the impact of all of the regional alternatives (regional airports and rail), on the future demand for Logan and the need for Airside Project improvements
- Reporting on the status of proposed ground access improvements at Logan, Manchester, T.F. Green / Providence and Worcester Regional airports
- Summarizing the documented environmental impacts of growth at the regional airports (See Appendix B of this Supplemental DEIS / FEIR)

The findings of this expanded regional analysis are consistent with the conclusions of the Airside Project Draft EIS / EIR: (1) even with increased utilization of the regional airports and high-speed rail, the demand for Logan services generated within its primary market area (inside I-495) will continue to grow; (2) in light of this continuing demand for air service out of Logan, delays will not improve solely as a result of increased utilization of regional airports and high-speed rail; and (3) Logan's current and projected level of delay can be relieved only through the additional Airside Project improvements that comprise the Preferred Alternative.

2.2 The New England Regional Airport System

2.2.1 Logan Airport's Role in the Regional Airport System

Boston is the largest metropolitan area and the center of commercial activity in New England. In 1999, there were 3.9 million people residing in the Boston metropolitan area, or 29 percent of New England's total population (Figure 2.2-1). Boston's high concentration of people, businesses, and attractions, makes it the largest generator of inter-city passenger trips in the region. Since air travel demand is primarily a function of the local population base, income levels, and economic activity, Boston's Logan Airport has naturally developed into the largest and busiest airport in the six-state region.

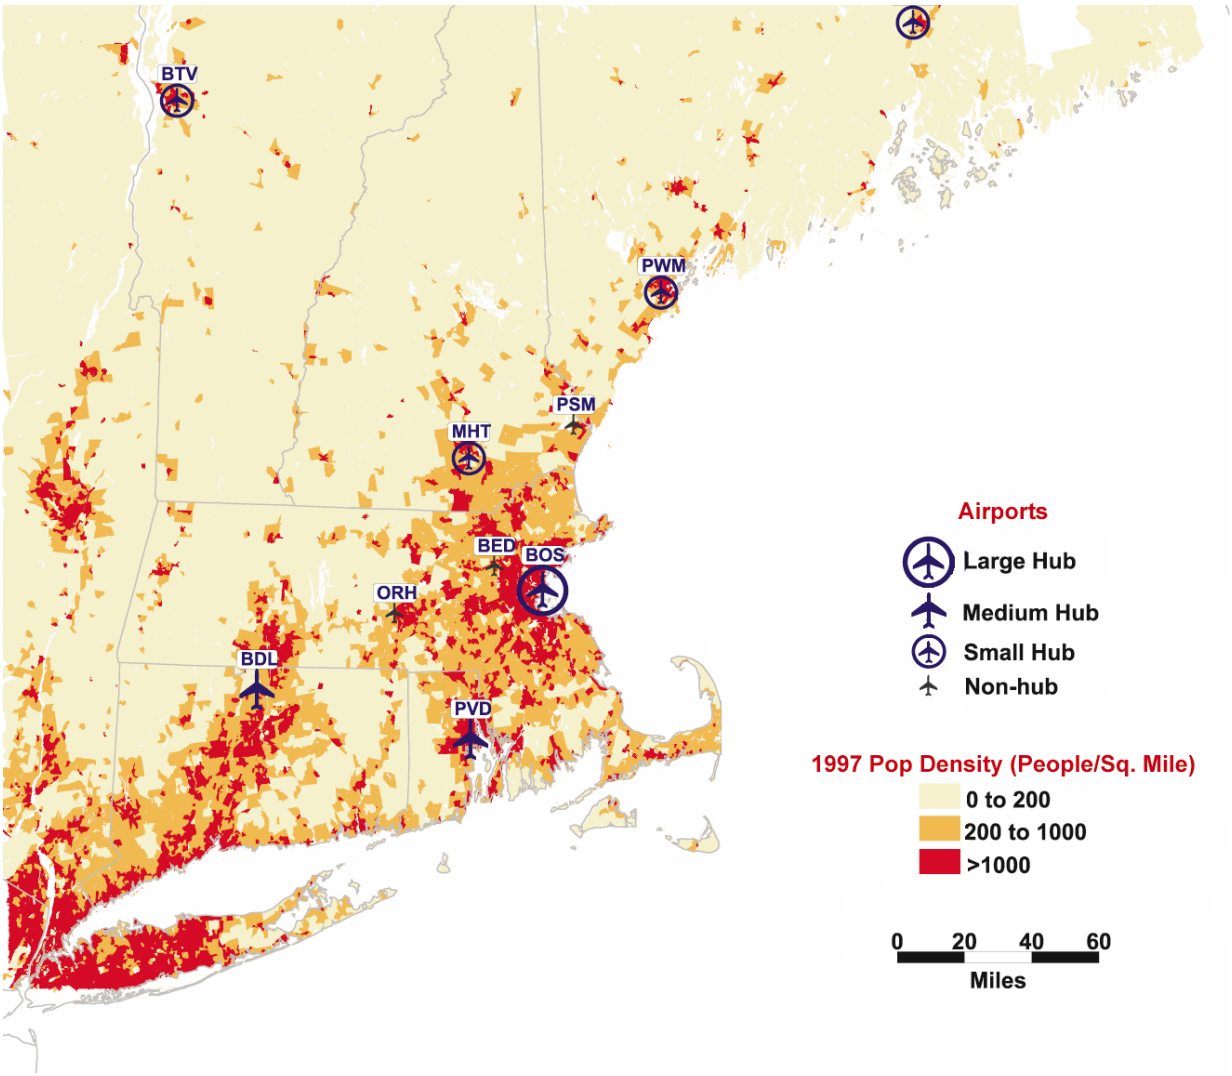


Figure 2.2-1

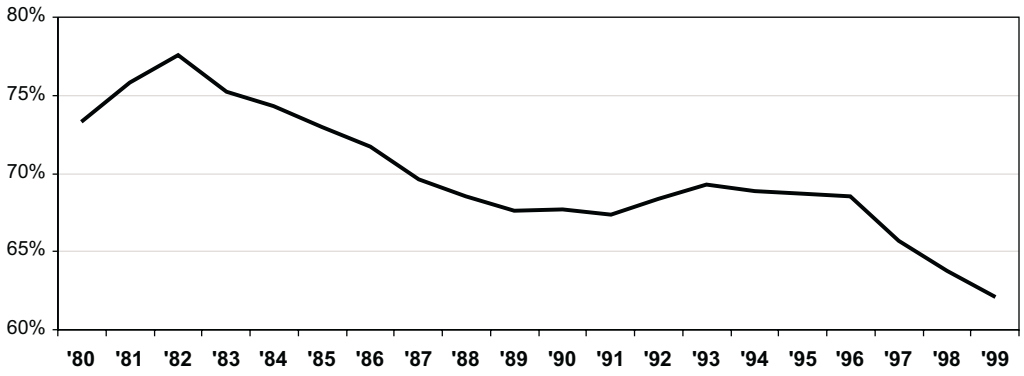
New England's Population is Highly Concentrated in the Metropolitan Boston Area

7466-FIG-2.2-1.p65

As Figure 2.2-2 shows, Logan historically has accommodated most of the air passenger activity in New England, in addition to the demand generated by the Boston area. In the early 1980s, Logan accounted for a disproportionate share of the region's air travel demand capturing more than three-quarters of New England's air passengers. By the late 1980s, Logan's passenger share declined to 68 percent as airlines responded to deregulation by adding services to other New England airports. However, in the early 1990s, when economic conditions weakened, air travel demand declined throughout the region. As a result, the regional airports failed to gain ground and Logan's passenger share remained constant at around 68 percent.

Figure 2.2-2
Logan's Share of Passenger Enplanements in New England



Note: Includes enplaned passengers at Logan, Hartford/Bradley, T.F. Green/Providence, Manchester, Portland, Burlington, Bangor, Tweed New Haven, and Worcester.

Source: US DOT, Form 41 and Part 298/C. Airport records for Logan and various regional airports.

Recognizing that the region's demand for air travel would grow over time and that Logan was becoming increasingly delayed, transportation planners began to develop regional transportation strategies to actively promote growth at the region's other airports and to develop alternative modes to air travel. Since 1989, a series of transportation planning studies, which are summarized in Table 2.9-2, examined regional transportation options for accommodating future demand. Many of these studies were cooperative efforts that reached across transportation agencies and state borders and involved public participation.

The outcome of the regional transportation studies was a shared commitment among the New England states, Massport, and other transportation agencies to develop and promote inter-city travel options throughout the region. Recommendations included increasing the use of underutilized airports and developing high-speed rail as an alternative mode to air travel. The studies also recognized Logan's central role in the region's intercity travel network and consistently concluded that landside and airside infrastructure improvements, which would improve the efficiency of Logan, were a critical component of a successful regional transportation strategy.

Many of the regional transportation strategies articulated by these studies are being implemented and are having a meaningful impact on intercity travel to and from New England. In terms of air travel, the region has further reduced its reliance on Logan Airport. In 1999, Logan enplaned 62 percent of the region's air passengers compared to 68 percent in 1990 and 78 percent in 1980. The decline in Logan's share is a result of coordinated efforts to increase air service options at the regional airports.

The growth exhibited by the regional airports is changing the role of Logan within the broader regional airport system. In the new regional environment, Logan is serving two primary functions. First, because of its proximity to the greatest concentration of travel demand in the region, Logan is the primary airport for passengers originating within Interstate 495. Logan is the best airport for serving the majority of the air travel needs of these passengers. It is not only the closest airport for most of these passengers, but it receives service from more airlines to more destinations than any other airport in New England.

Logan also functions as the primary airport for the long-haul[4] domestic and international travel needs of the entire region. Currently, there is only a single daily flight from a regional airport to a long-haul domestic market[5] and no scheduled flights to overseas destinations. Long-haul services have not developed at the regional airports, because the areas served by the regional airports lack a sufficient base of demand for travel to these destinations as well as connecting traffic. Opportunities for future growth in long-haul domestic and international services at the regional airports will be explored in the upcoming New England Regional Airport System Plan. For the foreseeable future, Logan is the only airport in New England that can serve as an international gateway for the region.

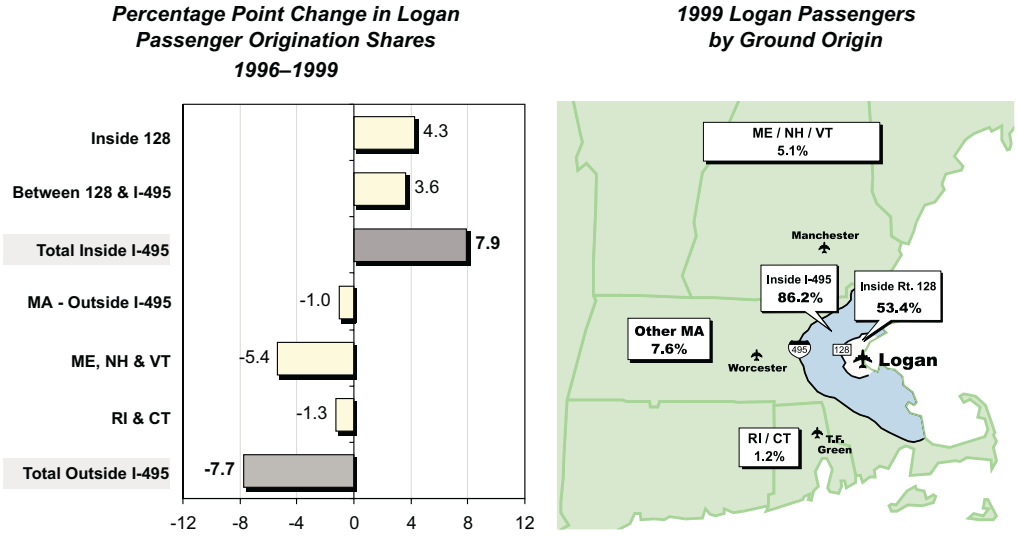
Logan's role as the primary airport for passengers that originate outside of I-495 has already diminished and is expected to diminish even further over time. Several of the regional airports have made considerable gains in obtaining direct services to short-haul high density markets and airline connecting hubs. Massport and the regional airport authorities are working together to ensure continued growth in air services at the regional airports.

The Logan Airport 1999 Air Passenger Survey, which tracks ground origin patterns of Logan Airport passengers over time, indicates that the geographic area which Logan serves has narrowed over time. As Figure 2.2-3 shows that in 1993 and 1996, approximately 20 percent of Logan's passengers originated from cities and towns outside of I-495. The most recent survey shows that in 1999 the share of Logan's passengers originating outside of I-495 decreased to just over 14 percent. These data confirm that aggressive service expansion at the surrounding regional airports is diverting passengers from Logan to the regional airports. The 1999 Air Passenger Survey data implies that approximately 2.4 million air passengers opted to use one of the regional airports instead of Logan.

4 Long haul markets are markets that are over 1,500 miles in distance.

5 Southwest Airlines operates a daily flight from T.F. Green/Providence to Houston Hobby Airport in Texas. Additional long-haul domestic services are available at the Hartford/Bradley Airport, but, because of distance, this airport is not an option for air travelers in the Boston metropolitan area.

Figure 2.2-3
Logan's Passenger Demand is Concentrated within I-495



Source: Massport Logan Passenger Survey, 1996, 1999

In addition to expanded service options at the regional airports, high-speed rail is also expected to relieve some of the burden on Logan Airport. On December 11, 2000, Amtrak initiated its high-speed Acela service, between Boston's South Station and New York's Pennsylvania Station offering passengers an alternative mode to air travel. This service, which continues on to Washington, DC represents an attractive and competitive option to high-speed air travel in the Northeast Corridor. As this service develops and more trains are added to Amtrak's schedule, as many as 1.2 million passengers[6] are expected to switch from air travel to rail travel, further reducing the region's reliance on Logan for travel to short-haul markets.

2.2.2 The Role of Regional Airports

In addition to Logan, the New England region is also served by several smaller commercial service airports throughout the six-state area (see Figure 2.2-4).[7] The regional airports closest to Logan's core service area, defined as the region within Interstate 495, have the greatest potential for serving some of the demand that has historically used Logan Airport. These airports include the T.F. Green / Providence Airport to the south, Manchester Airport to the north, and Worcester Regional Airport to the west. In 1999, these airports accommodated a combined total of 8.0 million passengers, approximately 30 percent of Logan's passenger traffic. These have been among the fastest growing airports in New England. In 1997 and 1998, T.F. Green / Providence Airport and Manchester Airport, respectively, were the fastest growing airports in the nation. In

6 Final EIS/EIR and 4(f) Statement, Northeast Corridor Improvement Project, U.S. DOT, Federal rail Administration, October 1994.

7 The *New England Regional Airports Air Passenger Service Study* defined the Hartford, Providence, Manchester, Portland, Bangor, Burlington, Worcester and New Haven airports as the region's principal commercial airports, other than Logan Airport, since all of these airports either supported or had previously supported commercial jet passenger services. Limited commercial passenger service was subsequently introduced at Hanscom Field in Bedford, Massachusetts and at Pease International in Portsmouth, New Hampshire in 1999. Commercial service at Hanscom Field is on regional airline turboprop aircraft while Portsmouth is served with jet aircraft.

2000, passenger traffic at Worcester Regional Airport more than doubled as a result of Massport's aggressive efforts to attract new airline services to Worcester. The remarkable growth at these airports signals an important change in how the region's air travel demand is accommodated. Through extensive investments and growth in new, competitive services, the regional airports have become attractive service options and are capturing increasing numbers of passengers that have historically relied on Logan Airport.

In 1999, Manchester and T.F. Green / Providence remained the fastest growing airports in New England, with passenger levels increasing by 45 and 11 percent, respectively, over 1998 levels (see Table 2.2-1). Hartford / Bradley International, the largest of the regional airports, grew by only 2.1 percent in 1999, but growth for 2000 increased to double digits due to the initiation of Southwest Airlines' service at the end of 1999. Over the past decade, the Worcester Regional Airport experienced a steep traffic decline, but that trend was reversed in 2000. New airline services initiated at Worcester Regional Airport in February and July 2000 caused passenger activity levels to more than double from 50,000 in 1999 to 106,000 by the end of 2000.

Source: The New England Regional Airports – 1999 Annual Summary, Massport.
* New England airports that have historically supported regularly scheduled passenger services.
** Enplaned plus deplaned passengers.
*** In 2000, Worcester Regional Airport passengers more than doubled from approximately 50,000 in 1999 to 106,000 passengers.
\+ Includes international passengers.

From 1996 to 1999, passengers using the regional airports increased by 13 percent a year, while passenger traffic at Logan Airport increased by only 2.5 percent annually (Figure 2.2-5). This is in contrast to the period from 1990 to 1996, when Logan's passenger traffic increased by 1.6 percent and the regional airports grew more slowly, at 1.0 percent per year. The significance of this is that, since 1996, the regional airports began to accommodate an increasing share of the region's passenger traffic.

The regional airports have been able to increase their share of the region's travel demand because airlines have begun to change the way in which they serve the region. Historically, the airlines concentrated their services at Logan and only offered limited air services at the regional airports. Regional airport services were infrequent, higher-priced, operated with smaller, less desirable turboprop aircraft, and required connecting flights to reach most destinations. In 1996, the regional airports, particularly T.F. Green / Providence and Manchester, began to receive significantly improved services, including lower-priced flights, more frequencies, and more direct jet flights, due in part to marketing efforts by individual airports, as well as cooperative marketing efforts. As a result, these airports have experienced exceptional air passenger growth (Figure 2.2-6).

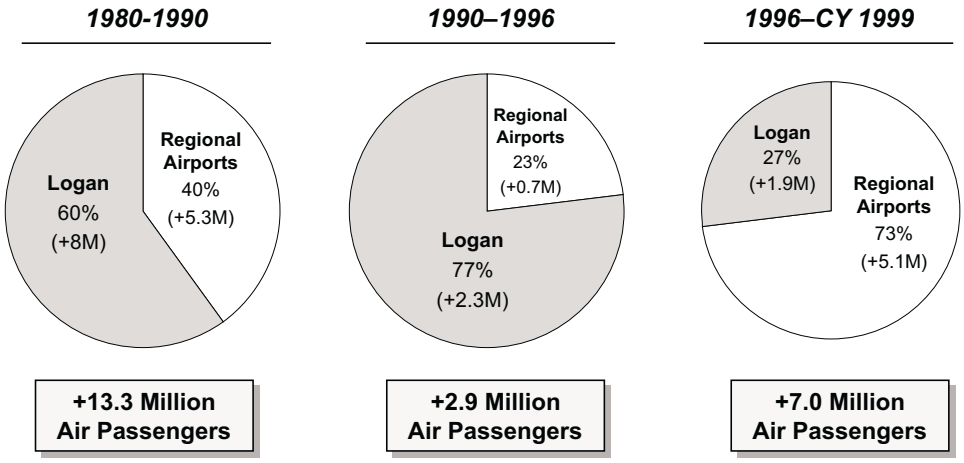
The groundbreaking *1995 New England Air Passenger Service Study*, which was the first study to assess air service opportunities from a regional perspective, identified the need for low-fare services at the regional airports. The study concluded that the introduction of low-fare, jet services would increase the utilization of the regional airports. If services at the regional airports were competitive with services at Logan, the regional airports would be able to attract passengers who originate within the regional airport service areas, but travel to Logan Airport for air service. This study led to the first cooperative air service marketing efforts in the region and a change in perceptions among airline planners as to how to serve the New England market.

Higher service levels have raised the profile of regional airports, particularly T.F. Green / Providence and Manchester, and transformed them into attractive options for many Logan Airport passengers. A major accomplishment has been the introduction of Southwest Airlines, the nation's premiere low-fare carrier, into the New England market. Southwest Airlines decided to avoid Logan Airport and to serve the Boston Metropolitan region by establishing operations at T.F. Green / Providence, Manchester and Hartford / Bradley International airports.[8] This is further evidence that Logan and the regional airports are operating as a regional system of airports.

As Figure 2.2-7 shows, since 1996, the regional airports have accommodated most of the air passenger growth in New England. During the 1980s and the early 1990s, Logan accommodated 60 to 77 percent of the region's new passenger traffic. More recently, from 1996 to 1999, only 27 percent of the region's passenger growth occurred at Logan Airport and 73 percent occurred at the regional airports.

Figure 2.2-7
Distribution of New England Passenger Growth – Regional Airports vs. Logan



Note: Regional airports include Providence, Manchester, Worcester, Bangor, Burlington, Hartford, New Haven, and Portland.
Source: Airport Records and US DOT, Form 41 schedules.

8 Southwest Airlines began service from Hartford/Bradley International Airport in 1999 with 12 nonstop departures per day.

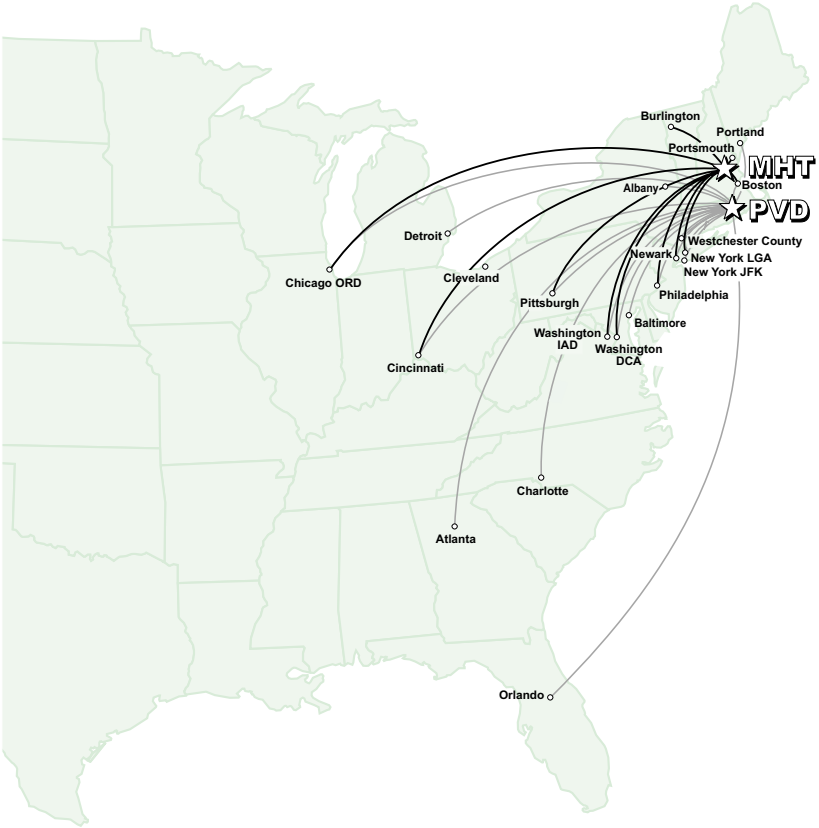
Regional airports are playing a larger role in serving the region's demand because they have benefited from substantial increases in air service offerings over the last three years. The airports that have benefited the most by achieving a critical mass of competitive services are the ones closest to the core Boston Logan Airport service area, i.e. T.F. Green / Providence and Manchester airports.

2.2.3 T.F. Green/Providence Airport

In October 1996, Southwest Airlines and Delta Express both commenced low-fare jet services at T.F. Green / Providence Airport.[9] Southwest Airlines, which strategically offers low-fare, short-haul, high-frequency, point-to-point service, is the nation's fourth largest airline in passenger boardings. Figure 2.2-8 displays non-stop service from Providence (and Manchester) to key destinations in the eastern US. Southwest Airline's entry at T.F. Green / Providence Airport was also its first entrance into the New England market.

Figure 2.2-8
Comparison of Nonstop Jet and Turboprop Markets Served from T.F. Green/ Providence and Manchester Airports– August 1995 and August 2000

August 1995 Service



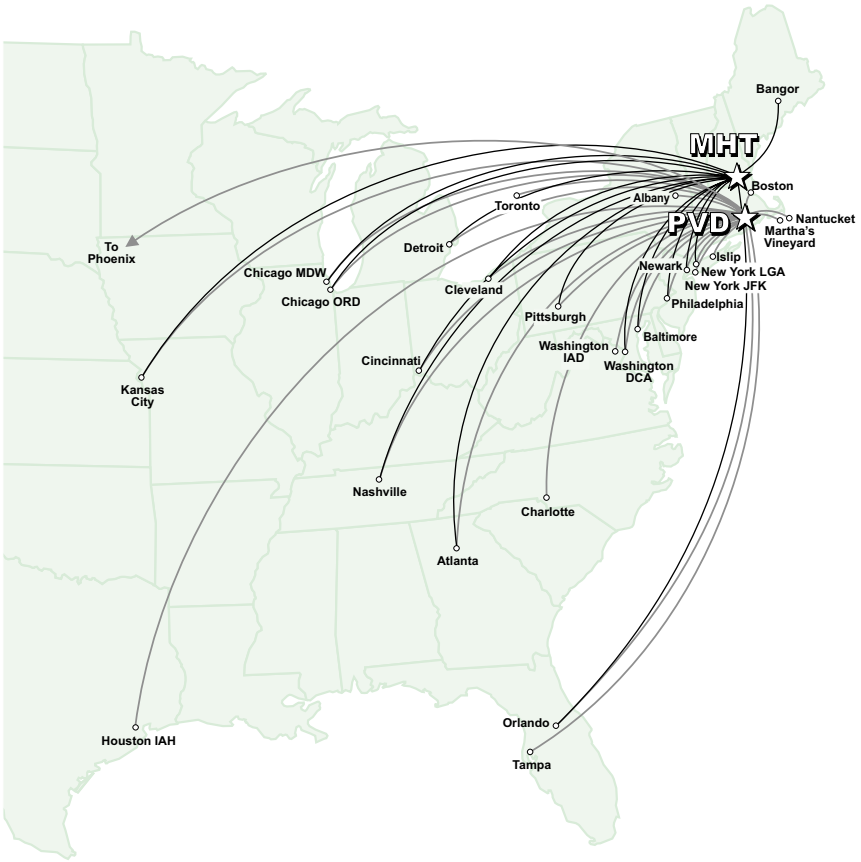
9 Both airlines initiated service in October 1996. Delta Express served the market for the entire month, while Southwest service commenced on October 27, 1996.

Southwest began its operation at T.F. Green / Providence Airport with 14 daily, nonstop flights to several key business and leisure markets: Baltimore / Washington, Chicago Midway, Orlando, Tampa and Nashville. By December 1999, Southwest Airlines increased its overall services at T.F. Green / Providence to 23 daily, nonstop departures. In 2000, Southwest Airlines continued to expand its services and now provides 27 daily, nonstop departures from T.F. Green / Providence.

Also in October 1996, Delta Express, a low-fare subsidiary of Delta Air Lines, inaugurated low-fare jet services at T.F. Green / Providence, providing two daily, nonstop flights to Orlando and a daily, one-stop flight to West Palm Beach.[10]

Figure 2.2-8 (Cont'd)
Comparison of Nonstop Jet and Turboprop Markets Served from T.F. Green/ Providence and Manchester Airports– August 1995 and August 2000

August 2000 Service



10 Delta Express service between T.F. Green and West Palm Beach was subsequently discontinued.

Other significant service improvements at T.F. Green / Providence Airport are as follows:

- In June 1998, US Airways' low-fare service operation, MetroJet, entered the T.F. Green / Providence market with six daily nonstop flights to Baltimore, with connecting services to Florida destinations. By August 1998, MetroJet had increased its service to seven daily, nonstop departures from T.F. Green / Providence Airport.
- In 1998, Air Ontario, an Air Canada regional commuter carrier, began serving the Providence-Toronto, Ontario market with three, daily, roundtrip, non-jet commuter flights.
- In 1999, Continental Airlines began offering nonstop service to Houston. It also supplemented its nonstop Cleveland jet service with two daily roundtrip flights on regional jets. In 1999, Continental upgraded its nonstop services to Newark from turboprop to large jet aircraft.
- In 2000, Southwest Airlines added four daily nonstops services to Islip and one daily nonstop service to Phoenix.
- Also in 2000, Atlantic Coast, a regional partner with United Airlines, upgraded its service to Washington Dulles Airport from turboprop to regional jet aircraft.

The introduction of these services to the Providence market has been highly successful. Between 1996 and 1999, passenger traffic at T.F. Green / Providence Airport increased by 2.7 million passengers. In 1997, the year after the beginning of Southwest Airlines and Delta Express services, the airport achieved 63.5 percent passenger growth, making it the fastest growing United States airport in 1997. In 1998, growth slowed to 13.7 percent, and in 1999, to 11.3 percent, but it is still well above the average growth rate for the New England region and the United States industry.

Over the last several years, the Rhode Island Airport Corporation (RIAC) and the FAA have made a number of capital investments at T.F. Green / Providence including:

- Construction of a $207-million terminal building with seven additional aircraft gates, and addition of a dual level roadway and access road.
- Construction of two 1,500-space parking garages to accommodate the increase in automobile traffic.
- Construction of various taxiway and runway improvements, including a Category II Instrument Landing System (CAT II ILS), to accommodate the increase in aircraft traffic.
- Construction of a new Federal Inspection Services (FIS) facility.
- On-going residential and school sound insulation.

RIAC is about to embark on a new airport master plan for the T.F. Green / Providence Airport to address future airport needs. This will be, at least, a 2-year effort that will consider the feasibility of extending both runways.

2.2.4 Manchester Airport

In June 1998, Southwest Airlines continued its expansion into the New England market by inaugurating services at Manchester Airport in New Hampshire. The airline began serving Manchester with 12 daily, nonstop flights to key markets including Baltimore / Washington, Chicago Midway, Nashville and Orlando. By 1999, Southwest Airlines added one daily, nonstop flight to Kansas City, totaling 13 daily departures.

In June 1998, MetroJet also commenced services at Manchester Airport. MetroJet offered four daily, nonstop jet departures to Baltimore / Washington, with connecting services to Florida destinations. By August 1998, MetroJet increased its nonstop Baltimore service to five daily, nonstop flights.

Other key service improvements at Manchester Airport are as follows:

- In 1998, Northwest Airlines introduced three daily, nonstop jet flights to its Detroit connecting hub; by 2000, it increased its service to five daily flights during the peak travel months.

- In 1999, Continental Express inaugurated twice-daily, nonstop service to Cleveland with regional jet aircraft. In 2000, Continental upgraded its Manchester-Newark services from turboprop aircraft to large jet and regional jet aircraft.

- In February 2000, Delta Air Lines added two daily nonstop regional jet flights to its Atlanta hub. Later in the year, Delta upgraded the service to large jet aircraft.

Consistent with the experience at T.F. Green / Providence Airport, the introduction of these services at Manchester substantially increased passenger traffic. Between 1996 and 1999, passenger traffic increased by 1.6 million passengers. In 1998, traffic increased by 73.6 percent over the prior year, making Manchester the fastest growing airport in the United States. Extraordinary growth at Manchester continued in 1999, with passenger traffic increasing by 45.4 percent over the preceding year.

Since the early 1990s, significant capital investments at Manchester Airport have included:

- Construction of a 158,000-square-foot passenger terminal.

- Construction of a six-level parking garage with a capacity for 4,800 cars.

- Construction of a new airport entrance road.
- Construction of a 97,000-square-foot general aviation terminal.
- Reconstruction / extension / instrumentation of Runway 6 / 24 from 5,000 feet to 7,000 feet.
- Construction of a new United States Customs facility.
- Ongoing residential sound insulation.

Most of the FAA funds for the development of Manchester's new terminal in the 1990s were discretionary funds provided by the Military Airport Program (MAP). MAP is a special feature of the Airport Improvement Program (AIP) allocated to former military bases that can serve to complement congested airports such as Logan Airport. Manchester Airport expects to handle five to seven million annual passengers by 2005. In November 2000, the Manchester Airport Authority announced plans to seek $121.5 million to fund additional airport development over the next five years. The plan calls for two terminal building additions, including a 70,000-square-foot addition, construction of a second parking garage, and roadway improvements. When completed in 2005, the project will have added eight additional aircraft gates. The second parking garage will be similar in size to the recently completed garage with more than 4,000 spaces. Recently the FAA announced approval of Manchester Airport's request for a Letter of Intent (LOI) of approximately $60 million over the next seven years to reconstruct and extend Runway 17 / 35 from 7,000 feet to 9,000 feet.

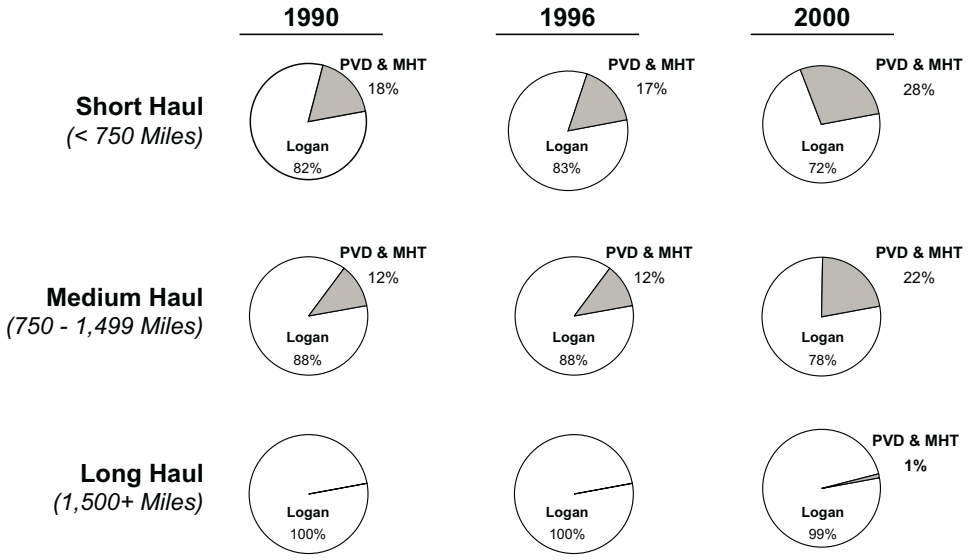
On the air service side, airport management is instituting an aggressive marketing program to attract new airline services to Manchester Airport.

2.3 The Complementary Roles of Logan and the Regional Airports in a Regional Airport System

The recent airline service expansions at the T.F. Green / Providence and Manchester airports are significant accomplishments from a regional planning and development perspective. The expanded service offerings have created true airport options for air passengers, and have effectively expanded the roles of these airports in serving the region's air travel demand. These airports now have a critical mass of low-fare, direct services to popular short- (under 750 miles) and medium-haul (750 to 1,499 miles) destinations giving many passengers that originate north and south of I-495 an attractive option to Logan Airport.

The T.F. Green / Providence and Manchester Airports now offer a considerable portion of the available airline services in the region. In 2000, the Providence and Manchester Airports provided 28 percent of available seat capacity to short-haul markets. Earlier, in 1990 and 1996, Providence and Manchester were providing less than 20 percent of short-haul seat capacity (Figure 2.3-1). Similarly, their service share to medium-haul markets rose from 12 to 22 percent, but their share of long-haul capacity increased to just one percent.

Figure 2.3-1
Share of Nonstop Seat Capacity by Market Distance – T.F. Green/Providence and Manchester Compared to Logan Airport for 1990, 1996 and 2000



* Based on Daily Seats for August of Each Year.

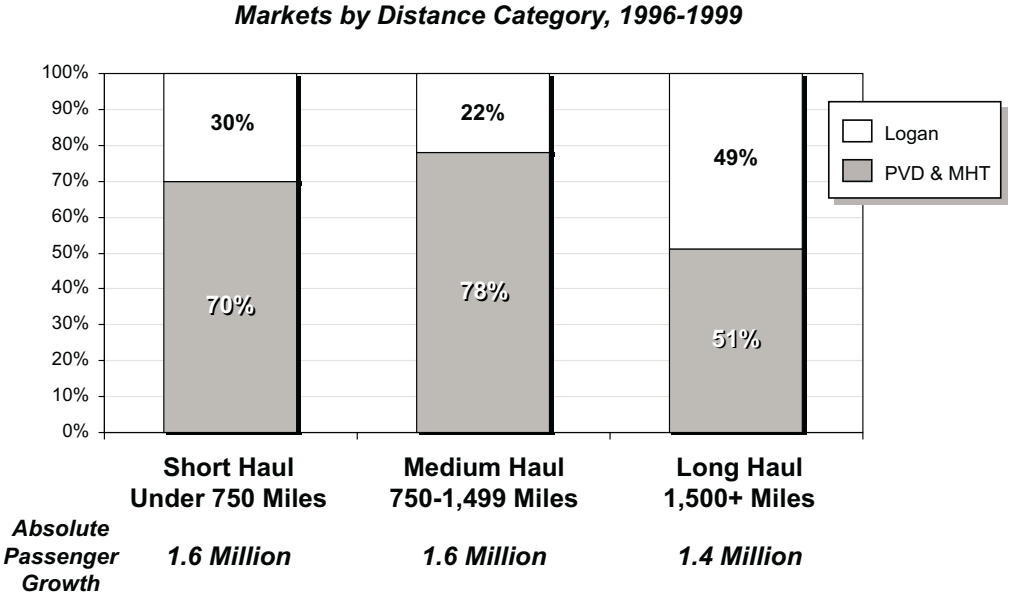
Source: Official Airline Guide, August 1990, 1996 and 2000

While the T.F. Green / Providence and Manchester Airports have increased their roles in the short- and medium-haul sectors, lower overall traffic densities within their respective market areas will prevent them from materially penetrating the thinner, long-haul market sector. Because of basic airline operating economics, Logan itself is served with fewer nonstop flights to long-haul markets, such as Los Angeles, compared to frequently traveled-to short-haul markets, such as New York. Hence, it is unlikely that the smaller, less-dense markets at T.F. Green / Providence, Manchester, and other regional airports could support a significant level of nonstop, long-haul services. Logan will remain the region's primary airport for reaching long-haul domestic and international destinations, while also serving the short- and medium-haul demand generated within its core market area (the area inside I-495).

By garnering a critical mass of services in the short- and medium-haul market segments, the T.F. Green / Providence and Manchester airports have been able to accommodate the majority of the region's passenger growth in these segments. From 1996 to 1999, short-haul demand generated by the three-airports increased by 2.3 million passengers. Seventy percent of this growth, or 1.6 million, new, short-haul passengers used the T.F. Green / Providence or Manchester Airports instead of Logan Airport (see Figure 2.3-2).

The substantial increase in medium-haul services at the two regional airports had a similar impact on airport usage. The three-airport system generated 2.0 million more medium-haul passengers, with the T.F. Green / Providence and Manchester Airports accommodating 78 percent of the increase, or more than 1.6 million passengers, as Figure 2.3-2 shows.

Figure 2.3-2
Share of Absolute O&D Passenger Growth in the Logan/T.F. Green/Providence/ Manchester Airport System – By Market Distance Category, 1996 - 1999



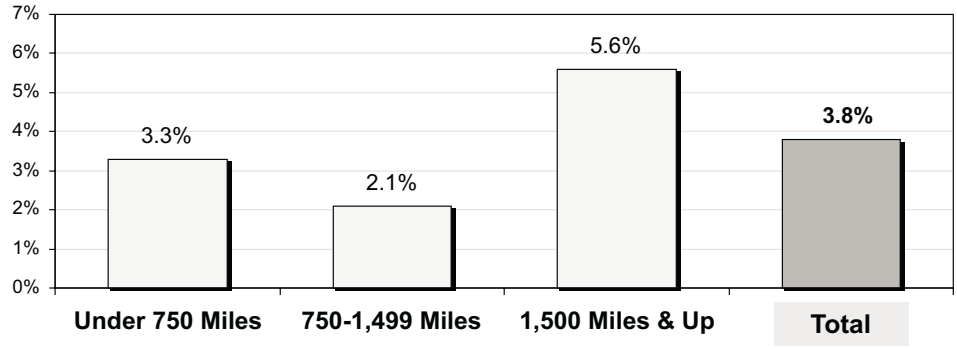
Source: USDOT, O&D Survey, and T-100.

The new traffic captured by the regional airports consists of untapped passenger demand stimulated by the introduction of low-fare services, passengers who shifted from ground modes to air because of the lower cost of air travel, and passengers who would have otherwise used Logan Airport, but switched to the regional airports because of new service offerings, competitive air fares and greater convenience.

Logan continues to be the primary airport for long-haul passengers (traveling to/from domestic and international markets), accommodating nine out of 11.2 million long-haul passengers generated by the three airports. From 1996 and 1999, the airport system generated 2.8 million additional long-haul passengers. Because Logan Airport leads the available services in this market segment, the regional airports attracted only half of this increase, or 1.4 million origin-destination (O&D) passengers, as Figure 2.3-2 shows.[11]

Figure 2.3-3 shows recent growth trends at Logan Airport which confirm that the region's reliance on Logan for travel to short- and medium-haul destinations is declining. From 1996 to 1999, the number of Logan Airport passengers traveling to short- and medium-haul markets grew relatively slowly at average annual rates of 3.3 and 2.1 percent, respectively. The number of long-haul passengers using Logan Airport grew at a faster rate, increasing by 5.6 percent per year.

Figure 2.3-3
Logan Airport's Average Annual O&D Passenger Growth by Trip Length to 1996 to 1999



Note: Includes reported domestic and international O&D passengers and estimated unreported foreign flag local passengers. Excludes connecting charter and GA passengers

Source: US DOT, Origin-Destination Survey, and T-100.

11 The majority of T.F. Green/Providence and Manchester passengers traveling to/from long-haul domestic and international markets require connecting service.

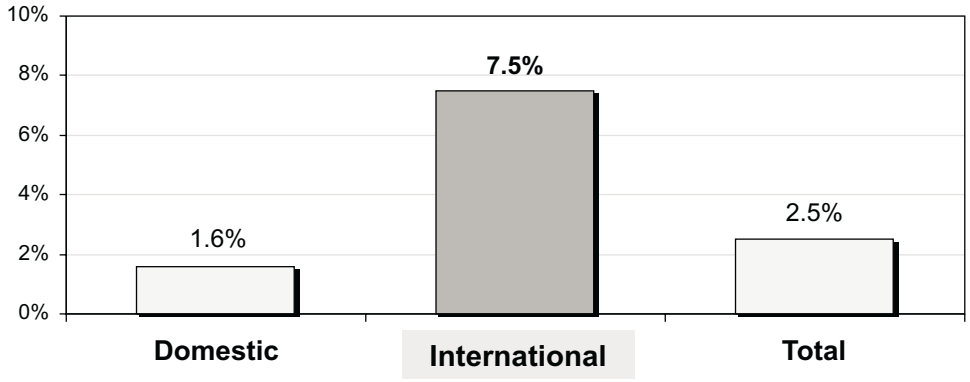
Figure 2.3-4 shows that Logan Airport's dominance in the long-haul sector is especially evident when examining its international traffic growth. From 1996 to 1999, the number of international passengers at Logan Airport increased almost five times as fast as domestic passengers. While total Logan Airport passengers increased by 2.5 percent per year during that period, international passengers grew at 7.5 percent per year and domestic passengers grew by just 1.6 percent per year.

Over time, long-haul traffic at Logan is expected to continue to grow faster than the short- and medium-haul market segments, solidifying its role in the regional airport system as the primary airport for long-haul travel.

Together, Logan and the regional airports will play essential roles in the emerging regional airport system. Logan Airport will remain the primary airport for passengers originating within I-495 and traveling to short-, medium- and long-haul destinations. The regional airports will play larger roles by functioning as the primary airports for short- and medium-haul demand that originates outside of I-495. Demographics, the distribution of demand within the region, and airline operating economics all dictate that Logan will continue to function as the region's primary airport for travel to long-haul domestic and international airports.

New England is well on its way towards achieving a true regional system of airports, but more can be done. Massport is working towards developing the Worcester Regional Airport to create a new airport option for passengers that originate in central Massachusetts and the western suburbs of Boston. The T.F. Green / Providence and Manchester Airports are engaged in development and planning efforts to ensure that they can continue to capture and accommodate passenger demand from their primary and expanded service areas.

Figure 2.3-4
Average Annual Passenger Growth at Logan Airport by Type of Service – 1996 to 1999



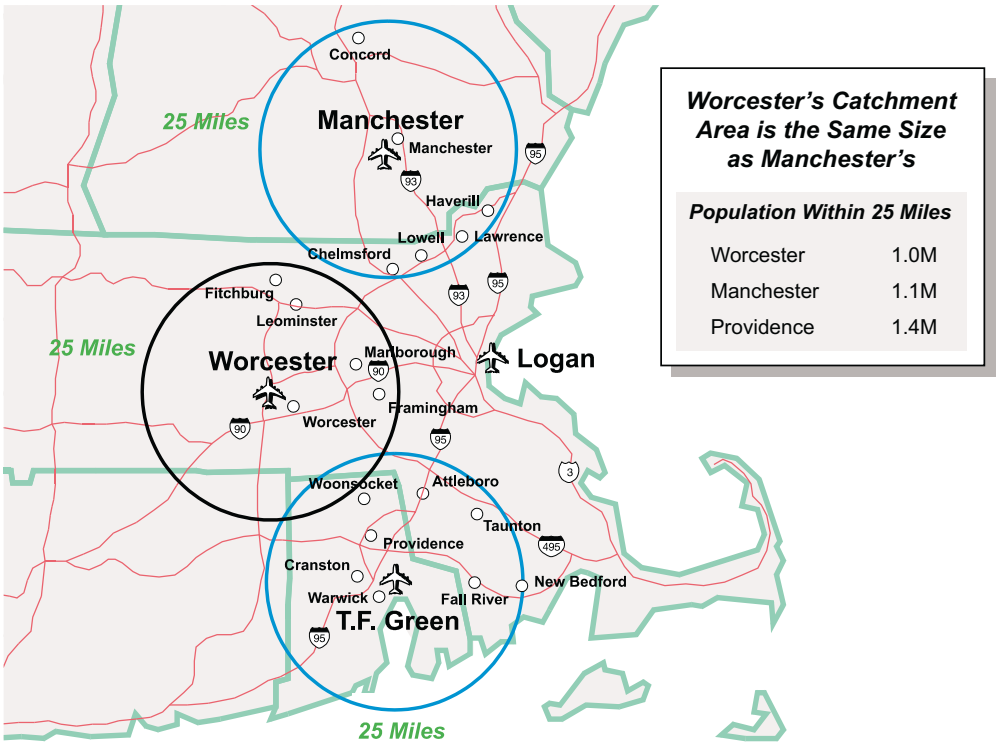
Source: Massport

The Pease Development Authority seeks to increase the role of the Pease International Tradeport in the regional transportation system and is aggressively marketing the facility to passenger and cargo airlines. Massport and the regional airports are undertaking cooperative marketing campaigns to increase passenger awareness of regional airport options to Logan. All of these efforts will move the region closer to the goal of a more efficient and balanced system of airports.

2.4 The Role of Worcester Regional Airport

T.F. Green / Providence and Manchester Airports are models of successful air service development that have contributed to the development of a regional system of airports in New England. Massport envisions the Worcester Regional Airport as the regional airport solution for air travel demand generated in central Massachusetts and the MetroWest suburbs. (see Figure 2.4-1).

Figure 2.4-1
Worcester Regional, T.F. Green/Providence, and Manchester Airports' Service Area and Location Relative to Logan Airport



2.4.1 Worcester Regional Airport Catchment Area

Worcester Regional Airport's natural catchment area is similarly sized to that of the Manchester Airport, which currently supports 50 daily jet departures to 15 destinations.[12] Each airport has a population base of about 1.0 million people residing within a 25-mile radius. For Worcester Regional Airport, this natural service area extends east to the Framingham / Natick area, north to Fitchburg, west to Belchertown, and south beyond the Connecticut and Rhode Island borders.

Four competitive airports are within an approximate one-hour drive of Worcester Regional: Logan is 46 miles east, T.F. Green / Providence Airport is 41 miles south, Manchester Airport is 67 miles north, and Hartford / Bradley International Airport in Windsor Locks, Connecticut is about 71 miles southwest of Worcester Regional. Since these larger, well-served airports are within a reasonable driving range, the Worcester Regional Airport must attract a competitive level of services that includes frequent jet flights and attractive airfares to compete with these nearby airports.

2.4.2 Worcester Regional Airport Service Area Demand

The Worcester Regional Airport service area, defined by a 25-mile radius, generates about 2.1 million annual origin-destination passengers.[13] This is an estimate of unconstrained demand, which essentially assumes equal access, service levels, and airfares for Worcester Regional and the surrounding airports. Since Logan Airport will continue to have a higher level of air services than Worcester, the Worcester Regional Airport will never capture 100 percent of its market area demand. However, in 1998, Worcester Regional Airport captured only three percent of its estimated passenger demand, indicating that the airport has substantial growth potential.

A survey conducted in 1999 of Worcester-area travel agencies and their airline ticket sales indicated that more than half of the demand generated within the Worcester Regional market area uses Logan Airport and almost one-third uses the T.F. Green / Providence Airport, as Figure 2.4-2 shows.[14]

The large portion of Worcester area passengers that uses Logan Airport indicates that service development at the Worcester Regional Airport would provide relief to Logan Airport. Similarly, the large portion of traffic using the T.F. Green / Providence Airport is an indication that T.F. Green / Providence is already providing relief to Logan Airport. Before the low-fare service expansion at T.F. Green / Providence, Logan Airport was capturing 80 percent of Worcester area passengers,[15] thus T.F.Green / Providence is capturing Worcester-area passengers that were formerly using Logan Airport.

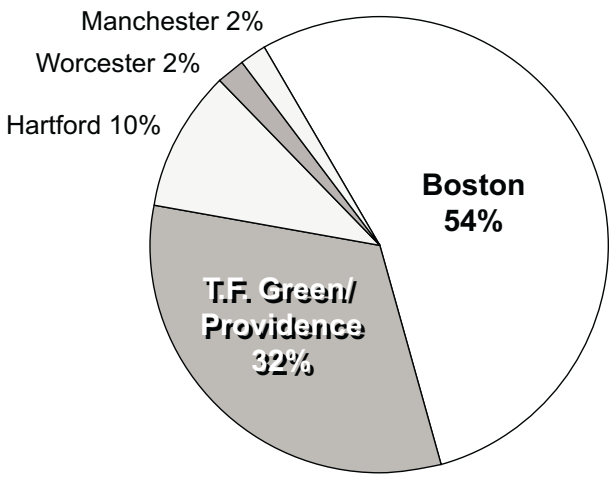
Figure 2.4-2
Worcester Area Passengers by Originating Airport - 1999 Travel Agency Ticket Lift Survey



Source: Worcester Ticket Lift Survey, 1999

The Worcester Travel Agency Ticket Lift Survey also revealed airport usage patterns by destination (see Table 2.4-1). It showed that Logan Airport was the airport of choice for key, short-haul, business markets capturing 51 to 70 percent of area passengers traveling to Washington, Atlanta, New York and Philadelphia. Offering a minimum of hourly service to each of these destinations, the carriers operating at Logan Airport provide a distinct advantage over the services provided by carriers at other airports.

Passengers traveling to markets with a lack of direct flights from the regional airports, such as Tampa, Ft. Myers, Dallas / Ft. Worth and St. Louis, most often used Logan Airport. T.F. Green / Providence attracted high shares of passengers (48 to 77 percent) in several markets, particularly destinations served with nonstop or multiple-stop flights on Southwest Airlines: Orlando, Chicago, Los Angeles, Detroit, Phoenix, and Baltimore.

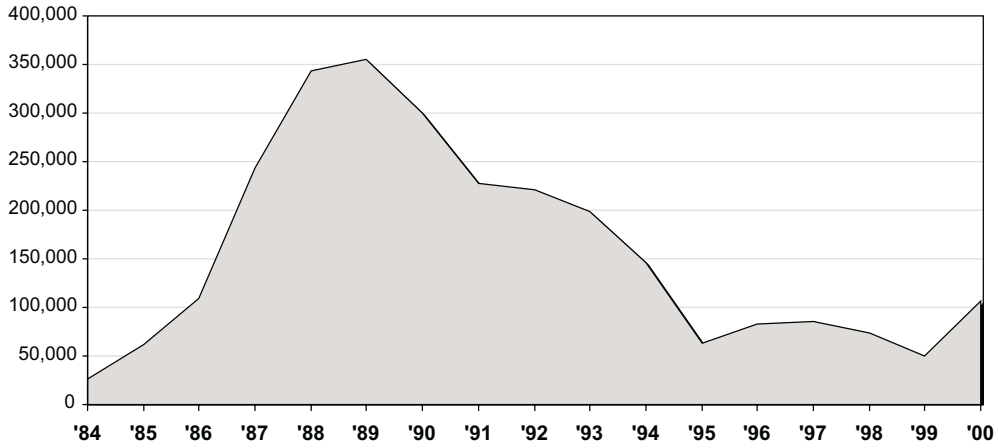
2.4.3 Worcester Regional Airport Air Traffic and Service Trends

Worcester Regional Airport has accommodated scheduled passenger service since the late 1940s.[16] However, these services were limited and passenger traffic grew only modestly. After reaching 90,000 passengers (enplaned and deplaned) in 1957, passenger levels declined until 1986. In that year, Worcester Regional Airport experienced brief unprecedented growth. Airport passenger traffic increased sharply from 58,000 in 1985 to a peak of 355,000 in 1989, as Figure 2.4-3 shows.

Between 1986 and 1989, Worcester Regional enjoyed exceptionally strong air traffic growth. This was a period of rapid growth in the local and national economies and of major expansion within the airline industry. In 1989, Worcester Regional received daily jet services to Baltimore, Newark, Detroit, and Pittsburgh.

16 Construction of the Worcester Airport was completed in 1948.

Figure 2.4-3
Worcester Airport Passenger Enplanements – Calendar Year 1984 to 2000



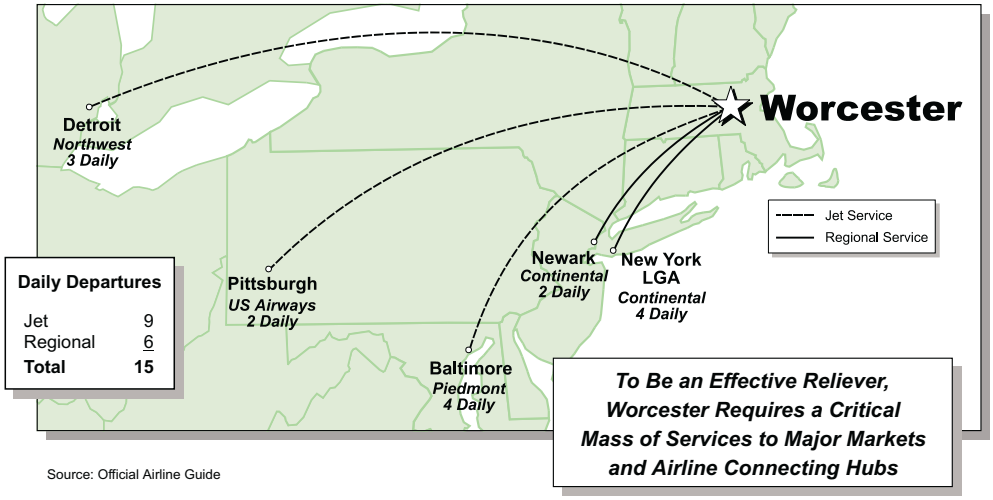
Source: USDOT, Form 41 - Schedule T3 and Part 298/C, and Airport Records.

Worcester Regional Airport's passenger traffic began to decline again in 1990, the same year that the Massachusetts economy entered a difficult recession. Massachusetts was particularly hard hit because the local economy was heavily tied to the defense and mainframe computer industries, which were also declining. At the same time, the airline industry was consolidating, which, coupled with slower economic growth and weakened air travel demand, led to severe financial losses. As airlines tried to rationalize their merged networks and stem financial losses, they withdrew services from many small communities like Worcester. Worcester itself was impacted by the 1990 merger of US Airways (then USAir) and Piedmont Airlines.

In 1993, the New England economy entered another period of prosperity, but passenger traffic at Worcester Regional Airport did not rebound to previous levels as other regional airports did. In 1999, 50,000 commercial airline passengers used Worcester Regional Airport, compared to its peak of 355,000 passengers in 1989. After aggressive marketing efforts by Massport, traffic at the Worcester Regional Airport more than doubled to 106, 000 passengers in 2000.

As Figure 2.4-4 shows, in its peak year, Worcester Regional Airport was served with 15 daily departures to nine destinations, nine on jet aircraft and six on turboprops. In 1989, Worcester Regional received scheduled passenger services from Piedmont (now US Airways), US Airways, Continental and Northwest Airlines. The airport had nonstop services to New York LaGuardia, Newark, Baltimore, Pittsburgh and Detroit. Worcester Regional Airport's peak level of service, however, proved to be insufficient to attract the necessary levels of passenger traffic to relieve growth pressures at Logan Airport or to establish Worcester Regional as a viable air service market. The resulting effects of this were the withdrawal of carriers from the market and the decline of traffic.

Figure 2.4-4
Worcester Regional Airport Nonstop Service - August 1989



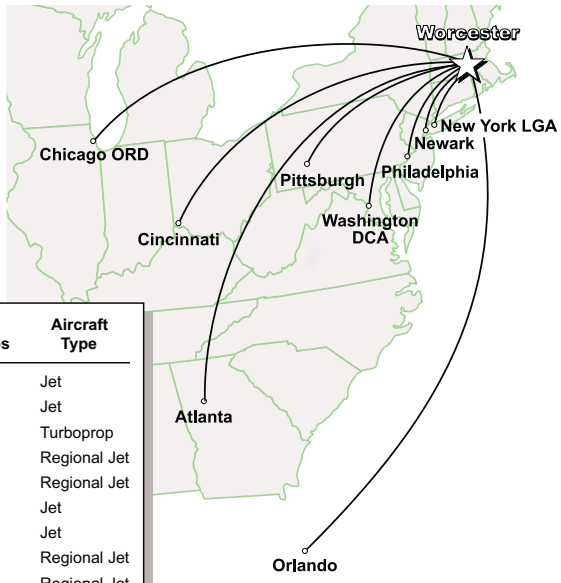
As of August 2000, the Worcester Regional Airport was served by three commercial passenger airlines. US Airways Express provides four daily, nonstop turboprop flights to Philadelphia. Atlantic Southeast Airlines, a Delta Connection carrier, provides two daily, nonstop regional jet flights to Delta Air Lines' Atlanta hub. Finally, American Eagle flies three times a day to New York JFK International with turboprop aircraft. In February 2001, Pan Am initiated nonstop service between Worcester and Orlando Sanford International Airport. In April 2001, Delta Connection will increase its service to Atlanta to three daily roundtrips.

In addition to general industry and economic conditions, facility, equipment, and ground access constraints also contributed to Worcester Regional Airport's decline and slow recovery. The sections below explore these constraints.

2.4.4 Worcester Regional Airport Service Feasibility

Worcester Regional Airport's past experience and the recent successes at T.F. Green / Providence and Manchester airports demonstrate that, to be an effective reliever in the regional airport system, the Worcester Regional Airport requires a critical mass of competitively priced services to key connecting hubs and major destinations. To assess Worcester Regional Airport's potential in serving the central Massachusetts and MetroWest passenger demand, the feasibility of potential Worcester Regional Airport air-service routes was analyzed. The carrier routes selected for feasibility analysis were based on existing air service patterns at the T.F. Green / Providence, Manchester, and Portland, Maine airports. Based on the same planning models and methodologies that airlines use to assess competitive market shares in a multi-airport environment, several jet, regional jet and turboprop routes were found to be feasible (see Figure 2.4-5). The analysis assumed convenient ground access to Worcester Regional Airport.

Figure 2.4-5
Candidate Worcester Regional Air Service Routes



Market	Carrier	Daily Roundtrips	Aircraft Type
Philadelphia	US Airways	4	Jet
Washington DCA	US Airways	2	Jet
New York LGA	Business Express	7	Turboprop
Chicago ORD	American	3	Regional Jet
Newark	Continental	4	Regional Jet
Orlando	Spirit	1	Jet
Pittsburgh	US Airways	3	Jet
Cincinnati	Delta	4	Regional Jet
Atlanta	Delta	4	Regional Jet

Candidate air service routes from Worcester Regional Airport would include service to short-haul, high density, business markets such as Washington Reagan National and New York LaGuardia; service to major airline connecting hubs such as Atlanta, Philadelphia, Pittsburgh, Chicago O'Hare, Newark, and Cincinnati; and low-fare service to leisure markets, such as Orlando. If just four to five of these candidate air-service routes were in place in 2010, Worcester Regional could achieve 600,000 to 800,000 passengers per year, depending upon the exact routes. At this level of activity, Worcester Regional Airport could potentially recapture about 300,000 to 400,000 passengers that otherwise would use Logan Airport.

2.4.5 Worcester Regional Airport's Ability to Attract Air Service

Several factors influence the ability of a regional airport, like Worcester Regional, to attract and sustain airline services. These include:

- The size of the airport's catchment area and the associated demand for air travel
- The proximity of alternative airports
- The availability of airside facilities
- Effective marketing efforts to attract both airlines and passengers
- Adequate ground access to the airport

In nearly all of these measures, Worcester is a favorable air service market. The market area of the Worcester Regional Airport is sizeable and generates approximately 2.1 million annual O&D passengers. However, because of its proximity to alternative airports, the Worcester Regional Airport requires a critical mass of air services in order to attract passengers from its substantial market area.

Massport, with the aid of an air service marketing consultant, is engaged in an aggressive marketing campaign to attract new airlines and passenger services to the Worcester Regional Airport. On January 15, 2000, Massport assumed actual operating responsibility for Worcester Regional Airport with the goal of developing a more efficient regional transportation network by increasing the airport's utilization. Massport has presented air service proposals to several airlines including Spirit Airlines, Jet Blue, American Trans Air, American Airlines, Delta Air Lines, Continental Airlines, Shuttle America, and Pan Am. Massport will continue these efforts, which have already resulted in several new services at Worcester:

- In February 2000, Atlantic Southeast Airlines (Delta Connection), a regional carrier subsidiary of Delta Air Lines, began serving Worcester Regional Airport market with two daily flights to Atlanta, with 50-seat Canadair Regional Jets. This service has been so successful, with passenger load factors reaching 94 percent in August, that Delta Connection is adding a third daily roundtrip in April 2001.

- In July 2000, American Eagle initiated nonstop flights to New York JFK International Airport. The service is operated three times per day, with 34-seat Saab 340 turboprops.

- On February 6, 2001, Pan Am began nonstop service from Worcester to the Orlando Sanford International Airport. This service operates once a day with Boeing 727 jet aircraft.

The FAA and the City of Worcester have invested $33 million in airside and landside improvements to upgrade the Worcester facility. In the mid 1990s, a $15.7-million passenger terminal was constructed and more than $8 million was invested in navigational equipment and airfield improvements to enhance the Airport's operational reliability.

As part of a regional transportation project, the Massachusetts Highway Department (MassHighway) is working to improve road access to the Worcester Regional Airport. A number of ground access routes that will improve access in the city and provide a connection between the airport and the inter-state highway system are being evaluated by MassHighway. A surface route would not only reduce congestion on major thoroughfares in the city and improve access to several western suburbs, it would also provide a safe, direct route from the Massachusetts Turnpike (I-90) and I-290 to Worcester Regional Airport. MassHighway submitted an ENF on the access road options to EOEA and received a Certificate from the Secretary on February 11, 2000. A combined Draft EIS/EIR is expected to be filed in October 2001. If approved, construction of a new road is expected to begin in 2004 and be completed by 2007.

The Worcester Airport is an example of how Massport is actively involved in promoting a regional airport system and the extent to which coordination with federal, state and local agencies can effectively promote and improve transportation options in the region.

2.5 Impact of Regional Alternatives on Logan Airport Demand

Despite the strength of the local and national economies, Logan's passenger traffic has grown more slowly than the United States average and the New England region for several years. The slower growth observed at Logan Airport coincides with extraordinary growth at neighboring regional airports.

The regional airports, particularly T.F. Green / Providence and Manchester, have become attractive options for many former Logan Airport users because of their proximity to the Boston metro area, lack of congestion, improved air service offerings, and low airfares. These airports will continue to dampen future growth at Logan by capturing a greater portion of the region's growth in air travel demand, particularly in the short- and medium-haul travel sectors.

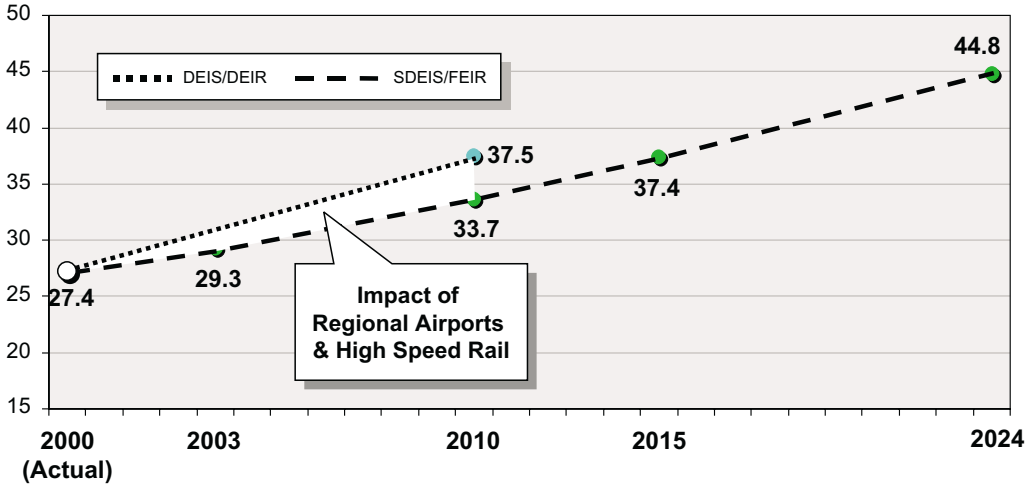
Also, many of the inter-city rail projects, which were discussed in the Airside Project Draft EIS/EIR, are closer to implementation. These projects, which include Amtrak's high-speed Acela service between Boston's South Station and New York's Penn Station, should also divert passengers from Logan Airport and reduce Logan's future passenger growth.

The increased role of regional airports and improved inter-city rail will continue to diminish passenger growth at Logan Airport. Based on this assumption, Massport has lowered its passenger growth projections. If growth continues at the slower rate observed over the last several years, Logan is expected to reach 34 million passengers in 2010 and will not achieve 37.5 million passengers until 2015 (Figure 2.5-1). This revised passenger forecast, which assumes that regionalization continues, is carried through the operational and environmental analyses in Chapters 4 and 6.

The operational analysis indicates that the proposed Airside Project improvements at Logan are necessary even with increased regional transportation options and significant passenger diversion from Logan to the regional airports and rail. While the expansion of regional transportation options will play an important role in reducing future demand for Logan Airport, it will not reduce passenger demand generated within Logan's core market area or the long-haul domestic and international travel demand of the broader region. The proposed Airside Project improvements, particularly the construction of Runway 14/32, are needed to improve the reliability, efficiency and safety of current and future operations at Logan. Runway 14/32 is the only measure that will correct the

existing limitation in Logan's airfield layout that causes excessive, yet avoidable, delays during northwest wind conditions.

Figure 2.5-1
Logan Airport Passenger Forecasts: Impact of Regional Transportation Options



2.6 Role of Other New England Commercial Airports

In addition to Logan, T.F. Green / Providence, Manchester, and Worcester Regional Airports, several other airports serve the New England region. These airports which are depicted in Figure 2.2-4, and described below, primarily serve areas outside the Boston Metropolitan Service Area in northern and southwestern New England. Because of their distance from Logan's core service area, the potential role that these airports can play in diverting demand from Logan is limited.

2.6.1 Hartford/Bradley International Airport, Hartford, Connecticut

The Hartford / Bradley International Airport is the second largest airport in New England after Logan Airport. Located in northern Connecticut, its primary function is to serve air passenger demand that originates in the southwest region of New England. Because of its distance from Boston and its proximity to New York, the Hartford airport primarily serves passengers that would otherwise use New York City airports, and has no potential to divert passengers from Logan Airport.

In October 1999, Hartford / Bradley International Airport became the third New England airport to receive Southwest Airlines' low-fare jet services. As of October 2000,

Southwest Airlines provides 13 daily departures from Hartford to Baltimore, Chicago Midway, Nashville and Orlando. Also in 1999, America West, another low-fare jet airline entered the Hartford market. America West provides one daily jet flight to Las Vegas, one daily jet flight to Phoenix, and three daily jet flights to Columbus, Ohio.

Over the last year, other carriers have also expanded services at Hartford. Delta Air Lines added one daily jet flight to New York JFK International; Midway Airlines added an additional flight to Raleigh / Durham; Continental Airlines upgraded its Newark flight to a larger aircraft; and US Airways upgraded its services to Baltimore from US Airways Express turboprops to MetroJet jet services.

Recent facility improvements at Hartford / Bradley International include renovations to Terminal B, the construction of a new FAA Tower, and a new firehouse.

2.6.2 Portland International Jetport, Maine

The Portland International Jetport, in Portland, Maine primarily serves the southern Maine area. The *1995 New England Airports Air Passenger Study* concluded that the Portland Airport had only a minimal ability to attract passengers that originate in Logan Airport's outer market area. However, Portland has historically relied on air services to Logan for connecting flights to destinations outside of New England. Thus, expanding air services at Portland can provide relief to Logan Airport by reducing the need for air services between Portland and Boston, which are often operated with small commuter aircraft. The economic feasibility of additional direct services from Portland will be analyzed in the upcoming *New England Airports System Study* (see Section 2.9.1, Table 2.9-3 and Appendix B for a description of the study and the proposed work scope).

In 1999, there was a decline in scheduled airline services at the Portland International Jetport compared to 1998. In terms of jet service reductions, Continental Airlines eliminated its daily nonstop service to Newark, United Airlines reduced it nonstop jet services to Chicago O'Hare from three daily roundtrips to 2, United discontinued one daily roundtrip to Washington Dulles, and US Airways reduced its Philadelphia service by one daily roundtrip. Among the regional carriers, both Business Express (now American Eagle) and US Airways Express reduced services to Boston and New York LaGuardia.

Since 1999, the Portland International Jetport benefited from several airline service additions. Continental Airlines added two daily, nonstop jet departures to its Cleveland connecting hub. Northwest Airlines increased jet services between Portland and its Detroit connecting hub. US Airways added an additional daily jet flight to Philadelphia and a new nonstop regional jet flight to Washington Reagan National. These additional flights at Portland reduce the need for Portland passengers to fly to Logan Airport for connecting services. In fact, in 2000 American Eagle (formerly Business Express) reduced its turboprop services between Portland and Boston by three daily roundtrip flights.

Capital investment projects for the Portland International Jetport include a new roadway system, a 50,000-square-foot terminal with two new gates and a ramp addition, and improvements to the Maine Turnpike-Jetport interchange.

2.6.3 Bangor International Airport, Maine

The Bangor International Airport, in Bangor, Maine, is even more distant from Logan Airport and the Boston market area than the Portland International Jetport, so it plays no role in relieving local passenger demand for Logan Airport. Because of its distance from Boston and its comparatively small population base, Bangor is even more reliant than Portland on air services to Logan Airport for connections to national and international destinations. Thus, improving air services at Bangor can reduce the need for direct air services to Logan Airport. The economic feasibility of these types of services will be analyzed in the upcoming *New England Airports System Study* (see Section 2.9.1, Table 2.9-3 and Appendix B for a description of the study and the proposed work scope).

In 1999, Delta Air Lines withdrew its mainline jet services at Bangor International Airport and replaced them with Delta Connection regional jets, operated by Comair, to Cincinnati. The change in Delta's service pattern eliminated single plane services from Bangor to Delta Air Lines's Atlanta hub and replaced two daily onestop departures to Cincinnati on large jets with four daily nonstops on regional jets. Other service changes included reductions in Continental Express services to Newark and US Airways Express services to Boston. Business Express added two daily nonstops to New York LaGuardia on non-jet aircraft.

In 2000, overall airline services increased slightly at the Bangor International Airport. Pan Am entered the Bangor market with nonstop services to Pittsburgh and Portsmouth, NH (Pease International). However, Bangor Airport lost several of its direct services to the New York / Newark area. Continental Express withdrew its two daily, turboprop flights to Newark and American Eagle discontinued two of its daily, nonstop, turboprop flights to New York LaGuardia. To compensate for these service reductions, US Airways Express added a nonstop flight to Portland with continuing single-plane service to New York LaGuardia; four daily, nonstop flights to Boston; and two daily, nonstop flights to Philadelphia.

Several facility improvements have been made at Bangor International Airport over the last several years. These improvements include taxiway improvements, the expansion of the commuter airline parking apron, the addition of enclosed passenger walkways, the rehabilitation of terminal and general aviation aprons, and the construction of a general aviation hanger. Over the next couple of years, the runway at Bangor International Airport will undergo major renovations to renew the life of the runway pavement.

2.6.4 Burlington International Airport, Vermont

Burlington International Airport is another distant airport that primarily serves air passenger demand originating in Vermont. Like other northern New England airports, it relies on air services to Logan Airport for connecting flights. To the extent that Burlington can attract more direct services to short-haul high density markets and airline connecting hubs, its reliance on air services to Logan will diminish. The economic feasibility of these types of services will be analyzed in the upcoming *New England Airports System Study* (see Section 2.9.1 and Appendix B for a description of the study and the proposed work scope).

In 1999, the Burlington Airport benefited from several service upgrades. US Airways replaced a non-jet service to New York LaGuardia with a regional jet service. Similarly, United Express replaced a non-jet flight to Washington Dulles with a regional jet. Continental Express initiated new nonstop regional jet service to Continental's Cleveland connecting complex.

In 2000, Burlington International Airport gained many new air services. JetBlue, the nation's newest low-fare jet carrier, entered the Burlington market with two daily, nonstop flights to its New York JFK hub. JetBlue, which former Southwest Airlines executives operate, is rapidly expanding its operations at JFK, offering connecting services to destinations throughout the country. Continental Express expanded its operation at Burlington International Airport by supplementing its turboprop services with regional jet flights to its Newark and Cleveland hubs. United Express upgraded its Washington Dulles services from turboprops to regional jets. Similarly, US Airways Express upgraded one of its flights to Washington Reagan National from a turboprop aircraft to a regional jet.

Several significant capital improvements to Burlington International Airport are in various stages of construction. A 17,000-square-foot expansion to the terminal building is under construction. Other projects include the addition of a commuter ramp extension to accommodate regional jets, and construction of a 40,000- square-foot maintenance hanger and a three-level parking garage.

2.6.5 Tweed-New Haven Airport, Connecticut

Located in southern Connecticut, the Tweed-New Haven Airport has no impact on Logan Airport. It is not close enough to Logan's core market area to provide any passenger relief and there are no scheduled services between New Haven and Logan Airport. Its service area largely overlaps with the Hartford / Bradley Airport service area.

In 1999 and 2000, the airline services offered from the Tweed-New Haven Airport have remained unchanged. The airport continues to receive eight daily, nonstop departures from US Airways Express. Five flights link New Haven to US Airways' Philadelphia hub and three nonstop flights are operated to Washington Reagan National.

The Tweed-New Haven Airport is currently conducting a Master Plan Study. In terms of capital improvements, an existing building has been modernized to serve as a new terminal.

2.6.6 Other New England Commercial Passenger Airports

In addition to New England's principal, commercial service airports, described above, there is another tier of airports that serve isolated communities or provide niche-commercial airline services. (Figure 2.6-1)

Several of these airports serve very small, remote communities that can only support services to Logan Airport. For these communities air service to Logan Airport is their sole access to the national air transportation network and destinations beyond Boston. These airports include Augusta, Presque Isle and Rockland, all in Maine. Other airports, such as Hyannis, Nantucket and Martha's Vineyard, serve higher-demand markets with services to Logan Airport and other major Northeast airports during the peak travel season. New Bedford, MA[17] and Westerly, RI, are only served with air-taxi operations to/from island markets (Nantucket, Martha's Vineyard and Block Island). Hanscom Field and Pease International did not receive scheduled passenger services until 1999. Both airports are now served with scheduled niche scheduled commercial airline passenger services.

Most of these airports are very remote from the core Logan service area and have limited market areas. Consequently, they are unable to support a sufficient level of air services to attract passengers that now use Logan Airport, and play virtually no role in relieving Logan Airport. Since Hanscom Field is part of Massport's proprietary airport system, it is somewhat of an exception and deserves further discussion. Because of the proximity of Pease International Tradeport, it also deserves further focus.

2.6.7 Hanscom Field

Hanscom Field, which Massport owns and operates, plays an important role in the regional transportation system as a general aviation reliever to Logan Airport with niche commercial passenger service. Hanscom Field accommodates a variety of general aviation operations, including private, business, charter and air taxi operations that might otherwise use Logan Airport.

17 Environmental analysis for the potential lengthening of the runway at New Bedford to accommodate integrated cargo services, as well as regional jet services, is currently underway. A Draft EIS/EIR is expected to be filed with MEPA and FAA/NEPA by the end of 2001.

Figure 2.6-1
Other New England Airports Receiving Commercial Air Passenger Service

Source: Official Airline Guide

In 1999, there were 197,302 general aviation operations at Hanscom Field, an increase of 7.7 percent over 1998 activity. Hanscom Field accommodated more than five times the number of general aviation operations that occurred at Logan Airport, which accommodated 38,000. Approximately 45 percent of Hanscom Field's operations were conducted with single-engine, piston aircraft. Training operations, which consist primarily of practice take-offs and landings by flight school students and staff, represented over 37 percent of Hanscom Field's operations. Business jets, twin-engine turboprop aircraft, helicopters, and military aircraft accounted for the remainder of the activity.

Even when its training activity is excluded, Hanscom Field handles more than three times the number of general aviation operations that occur at Logan Airport. Moreover, there are about 400 general aviation aircraft based at Hanscom Field, while there are none based at Logan Airport. For many general aviation users, Hanscom Field is a more attractive facility than Logan Airport because it has lower user fees and less restrictive airspace. Massport does not require general aviation users to pay a landing fee at Hanscom Field,[18] whereas Logan Airport users are required to pay a landing fee. These factors divert many operations from Logan Airport to Hanscom Field each year, as the substantially higher volume of general aviation activity at Hanscom Field indicates.

In September 1999, Shuttle America, a new entrant regional/commuter airline began scheduled commercial passenger service from Hanscom Field to Trenton/Philadelphia and Buffalo (one stop via Trenton) with four daily, roundtrip flights on 50-seat Dash-8 turboprop aircraft. In 1999, Hanscom Field accommodated 22,924 Shuttle America passengers and 1,164 Shuttle America aircraft operations. In 2000, the first full year of Shuttle America's Hanscom services, there were 162,147 scheduled service passengers and 6,572 scheduled operations at Hanscom Field. In October 2000, Shuttle America scheduled four daily, nonstop flights to Buffalo and seven to Trenton/Philadelphia. On November 1, 2000, Shuttle America began serving the Hanscom Field-LaGuardia market with five daily roundtrip flights and increased its Hanscom–LaGuardia service from five to seven daily roundtrips in February 2001.

Because the service areas of Logan, Manchester and Worcester Regional Airports envelope Hanscom Field's service area and there has been rapid low-fare service development at Manchester Airport, Hanscom Field will continue to be a general aviation reliever for Logan Airport, while offering niche commercial airline flights, such as the Shuttle America services.

2.6.8 Pease International Tradeport

In 1991, the federal government transferred operational authority for the Pease Air Force Base in Portsmouth, New Hampshire to the Pease Development Authority (PDA). Since assuming control over the former military base, the PDA has worked to develop the facility into an international aviation hub. A new, 20,000-square foot passenger terminal with a Federal Inspection Service facility and a Federal Trade Zone designation was built at the Pease International Tradeport. In addition to the terminal, the FAA has provided funds to rehabilitate the taxiway and apron, as well as upgrade/add the runway ILS and approach lighting systems. Like Manchester Airport, Pease has received, and continues to receive, MAP funds, which are allocated to former military bases that can serve to complement congested airports, such as Logan.

▼

18 Hanscom Field operations that occur between 11:00 PM and 7:00 AM are assessed a nighttime surcharge of $42.00 for aircraft under 12,500 lbs. and $306 for aircraft over 12,500 lbs. For operators with more than 5 violations (on arrival or departure) in a single year, the nighttime surcharge is doubled starting with the sixth violation.

The PDA is marketing the airport, which has an 11,300-foot runway in addition to its new passenger terminal and FIS facility, to large air carriers. With these new facilities, the Pease International Tradeport is potentially an attractive market for charter operators and cargo airlines. The potential long-term role of Pease International Tradeport will be evaluated in the *New England Airports System Study* (see Section 2.9.1).

In 1998, Pan American Airlines signed a long-term lease with the PDA, and, in 1999, it initiated scheduled and charter passenger service from the airport. Pan Am currently provides nonstop jet service to Orlando Sanford International Airport and Gary, Indiana. Emery Worldwide, an all-cargo airline, also serves Pease International Tradeport with one daily Boeing 727 freighter to Emery's Dayton, Ohio cargo hub. In addition to aviation uses, there has been tremendous growth in other land uses on the former military base which have contributed to the local economy.

2.6.9 General Aviation Reliever Airports

In addition to New England's regional commercial service airports there is another tier of airports that supports the general aviation component of the system. The role of these general aviation airports is appropriately identified in FAA's National Plan of Integrated Airport Systems (NPIAS) as "Reliever" airports. General aviation reliever airports typically are located and developed to attract the general aviation activity that would otherwise be active at a nearby congested airport. The Boston regional system has five such airports: Hanscom Field in Bedford, MA; Norwood Memorial in Norwood, MA; Beverly Municipal in Beverly, MA; Lawrence Municipal in Lawrence, MA ; and Boire Field, in Nashua, NH. Almost 1,000 aircraft are based at these airports and they accommodate about 750,000 operations annually. Runway lengths at these airports range in length from 4,000 feet to 7,000 feet, and except for Nashua, all have crosswind runways. They also have instrument capabilities to service non-precision or precision approaches. This reliever general aviation system receives priority consideration when FAA considers federal funding for capital improvement projects. Although no major improvements are planned for these facilities, there are on-going projects to maintain safe operations.

2.7 Other High-Speed Intercity Travel Options

2.7.1 Rail Service

In addition to the regional airports, several rail projects in the New England area will increase options for inter-city travel and create a more efficient and environmentally balanced regional transportation system. Table 2.7-1 provides the status of each of these projects and their potential impact on reducing air travel out of Logan Airport.

Table 2.7-1
Regional Rail Projects with Air Diversion Potential from Logan Airport

Project	Lead Agency	Description	Status	Projected Completion	Estimated 2010 Air Diversion
Northeast Corridor High Speed Rail	Amtrak	Reduce Boston to New York City rail travel times to four hours for Acela Regional Service and about three hours for Acela Express.	Completed	Acela Regional started January 2000 Acela Express started December 2000	1,220,000[1]
Portland-Boston Amtrak Service	Amtrak	Reinstate Portland, ME/Southern New Hampshire/ Boston North Station service using existing rail lines.	Completed	Service to begin in 2001	133,000[2]
Warwick/T.F. Green/ Providence Intermodal Station	Rhode Island DOT	Amtrak/Commuter Rail service from Boston South Station to Warwick Station with People Mover Connection to T.F. Green/ Providence Airport.	EA approved by FHWA in July 1999.	Construction to begin by late 2001.	128,000[3]
North Station-South Station Rail Link	MBTA	Construction of a rail tunnel to link North Station and South Station in Boston.[4]	Under environmental study	—	—
TOTAL					Up to 1,481,000

1 Latest publicly available data. Appendix B provides Amtrak's reply to request for updated numbers.
2 Interpolated from estimated 2015 diversion of 200,000 passengers annually.
3 Interpolated from 2000 and 2020 ridership estimates assuming 67 percent are non-airport employees (based on Survey of Warwick Intermodal Station at T.F. Green/Providence Airport Warwick, Rhode Island, May 1, 1999).
4 North-South Rail Link is not expected to be operational until after 2020.

Northeast Corridor High-Speed Rail

Of all rail projects, Amtrak's high-speed, Boston-New York Acela service offers the greatest potential for reducing Logan Airport's air travel demand in the Boston-New York corridor. By reducing the travel time between downtown Boston and downtown New York to about three hours, the Acela service will be an attractive alternative to the Boston-New York air shuttles for business passengers.[19] This will provide relief to Logan Airport by accommodating up to 1.2 million Logan passengers or one-third of the estimated future air-travel demand in Logan Airport's largest origin-destination market, the Boston-New York market. For more information on Northeast Corridor Amtrak Service see Sections 2.4.2.2 and 2.4.2.5 of the Airside Project Draft EIS/EIR.

19 While Acela service is an attractive option for Boston-New York air passengers, it is not competitive with air travel in the Boston-Washington market due to its longer distance (470 miles versus 250 miles for the Boston-New York City train) and uncompetitive travel time (6 hours, 30 minutes for Acela versus one hour, 40 minutes for air travel).

Boston-Portland, Maine Rail Service

In 2001, rail service between Boston and Portland, Maine will be restored. The service, called the "Downeaster," will be provided by Amtrak with conventional diesel locomotives reaching a maximum speed of 79 miles per hour. The service will terminate at Boston's North Station with stops in Woburn at the Woburn Regional Transportation Center (RTC), Haverhill, Dover, NH, Durham, NH, Exeter, NH, Wells, ME, and Saco, ME. Total trip time between Portland and Boston is projected to be two hours and 30 minutes compared to 2 hours by automobile. By 2010, with eight trains per day, the service is expected to divert approximately 133,000 air travelers by 2010

Warwick/T.F. Green Commuter Rail Station

An intermodal station is being developed at T.F. Green / Providence Airport in Warwick, RI. This station will provide a commuter rail link from Boston's South Station and the Route 128 Station to the Warwick, RI Station, with people mover access to T.F. Green / Providence Airport. This access improvement will allow more residents of the Boston Metropolitan Area to use the frequent, low-fare air services of T.F. Green / Providence Airport. It is estimated that this service will divert approximately 128,000 passengers from Logan Airport in 2010. The Environmental Assessment was approved in 1999. The design process is underway with construction slated to be completed by the end of 2002.

North-South Rail Link (NSRL)

A rail tunnel linking North Station and South Station, which is a Massachusetts Bay Transportation Authority (MBTA) initiative, has been under environmental review by the MBTA for several years. The proposed rail tunnel would improve the Boston metropolitan commuter rail system by allowing the MBTA to link both of its commuter rail systems and would improve intercity travel by allowing Amtrak to extend its Northeast Corridor rail service to North Station and beyond to the Woburn RTC. Early analysis indicated that the project could divert approximately 47,000 air passengers in the year 2020. Completion of the NSRL Draft EIR has been delayed because of a lack of funding for the project.

Northern New England High Speed Rail Initiative

In March 1999, the states of Massachusetts, Maine and New Hampshire filed a joint application with the Federal Railroad Administration to designate the Portland-Boston rail corridor a high-speed corridor. In August 2000, Massachusetts joined with Vermont and New Hampshire to file a similar application for the Boston-Montreal corridor (which would run diagonally across New Hampshire). Federal transportation officials approved both of these applications in October 2000, making the participating states eligible to apply for Federal money to fund safety and capacity improvements on higher-speed rail lines.

2.7.2 Video Conferencing

Section 2.4.3 of the Airside Project Draft EIS/EIR identified video conferencing as a potential substitute for business-related air trips. The Airside Project Draft EIS/EIR also noted that while video conferencing capabilities could reduce the need for certain business-related air trips, it was also likely to create new, global business opportunities and stimulate business-related air travel. Many analysts anticipate that video conferencing will result in a net increase in air travel demand. Thus far, the technology has failed to advance as quickly as telecommunications analysts had envisioned and has not been widely adopted by businesses. For this reason, Massport does not anticipate that video conferencing will have a material impact on Logan's air travel in the near term.

2.8 Ground Access Improvements at Logan and the Regional Airports

In his Certificates on the *Logan Airside Improvements Draft EIS/EIR* and the *1998 Annual Update*, the Secretary of Environmental Affairs directed Massport to report on the status of the ground access improvements at Logan Airport and at the primary regional airports that can relieve Logan Airport: T.F. Green/Providence, Manchester and Worcester Regional airports. Table 2.8-1 describes the major ground access projects at the regional airports.

The Secretary also directed Massport to quantify the impacts of these ground access improvements on passenger levels at the specified airports. Ground access enhancements can improve passenger convenience by reducing roadway congestion and travel times. However, adequate ground access is just one of many factors that affect a passenger's decision when choosing from multiple airport options. Other factors that override the ground access factor include airline services available at each airport: the number of daily flight frequencies; the timing and availability of the flights; whether the services are operated with jet or turboprop aircraft; airfares; the particular airlines that serve the airport; and whether the destination can be reached with a direct or a connecting flight.

Ground service improvement projects that improve access to airports that already benefit from convenient access, such as the widening of Route 3 north leading to the Manchester Airport, are not expected to materially alter airport usage patterns. Other ground access projects which offer alternative modes to an airport, such as the Silver Line or Airport Intermodal Transit Connector (AITC) projects that create bus links to Logan Airport, are also not expected to alter air passenger levels at Logan Airport. On the other hand, projects which conveniently link a congested airport service area to an alternative, less congested airport, such as the Warwick Intermodal Station, may have the potential to influence airport usage patterns. It is estimated that the Warwick Intermodal Station, which will provide a rail link from downtown Boston and the Route 128 station to the T.F. Green/Providence Airport, could divert up to 128,000 passengers annually from Logan Airport to T.F. Green/Providence (see Table 2.8-1).

Table 2.8-1
Ground Access Planning Initiatives at Logan, T.F. Green/Providence, and Manchester Airports

Initiative	Project Description	Lead Organization	Status Report	Projected Completion Date
Logan Airport				
Airport Intermodal Transit Connector (AITC)	Implementation of a Bus Rapid Transit Route to connect South Station with Logan Airport through the Ted Williams Tunnel. The project will use 60-foot, low-floor, articulated buses in conjunction with the Silver Line.	Massport	Fully approved. In process of selecting and purchasing vehicles. Service will commence as soon as the MBTA Transitway is completed. In the interim, the Logan DART bus service opened on November 16, 2000, and links South Station and the Logan Airport terminals.	2002
Silver Line	Three-part project to develop Bus Rapid Transit routes in Boston. Includes Washington Street Replacement Project, Transitway Phase 1 with tie-in to AITC and Transitway Phase 2.	MBTA	See Below.	
Silver Line: Transitway Phase 1	Includes one-mile tunnel and surface sections to be operated by dual-mode (electric/diesel), articulated buses. Massport will use eight of the vehicles ordered for the AITC to connect South Station with Logan Airport through the Ted Williams Tunnel.	MBTA	Construction has begun on a $600M bus tunnel to connect South Station to the South Boston Waterfront.	Not earlier than 2001
Silver Line: Transitway Phase 2	Bus Rapid Transit route to connect Washington Street Replacement Project with Transitway Phase I. Tentatively planned to connect with Boylston and Chinatown MBTA subway stations.	MBTA	In September 2000, construction for the Dudley Square to Chinatown segment began. At a cost of $52M, project will be completed in 2003. Funding for the Chinatown to South Station tunnel is expected in 2004 with construction completed by 2008.	2004-2008
Fourth Logan Express	Planning is underway for a fourth Logan Express location which would serve the North Shore, areas of northeastern Massachusetts, southern New Hampshire, and southeastern Maine. Massport is currently considering a candidate site and moving forward with conceptual design of this facility.	Massport	Site identification and feasibility study underway	Late 2001
Urban Ring	Currently, a series of cross-town bus routes linking low-income and developing Boston area neighborhoods with access to MBTA subway lines. Long-term vision would see the project develop into light rail or dedicated bus ways. One of these cross-town bus routes, the CT3, currently goes from the Longwood Medical area through Roxbury to Logan Airport.	MBTA	In study phase. Implementation not expected for several years.	
Worcester Regional Airport				
Worcester Access Road Improvements	Improvement of access to Worcester Regional Airport from nearby interstate highways. The Regional Access Improvement Study, prepared for the MassHighway in October 1998, identified three feasible alternatives to construct new highways, construct short linking segments and develop existing roads.	MassHighway Department	Project is in the pre-permitting stage. Alternative routes are being analyzed and discussed with the City of Worcester. An ENF was filed, and a Certificate issued on February 11, 2000. A combined Draft EIS/EIR is anticipated to be filed in October 2001, with a Final EIS/EIR filed in Spring 2002.	2004-2007
T.F. Green/Providence Airport				
Warwick Intermodal Station at T.F. Green/ Providence Airport	Proposed construction of an Amtrak/ Commuter Rail Station on the Northeast Corridor with a people mover connection to T.F. Green/Providence Airport. Most likely scenario includes moving sidewalk similar to new Logan Airport pedestrian ways; and horizontal elevator similar to Wellington Shuttle in Medford, MA. The governors of RI and MA signed a formal agreement that will allow the MBTA to extend Commuter Rail service to the station when it is completed.	Rhode Island Department of Transportation	Environmental Assessment, which was completed in July 1999, received a Finding of No Significant Impact from the Federal Government. Conceptual design for the project is underway. The City of Warwick and RI Economic Development Council have issued an RFP to develop land near the station. Design work for the station will coordinate with development efforts. Station construction anticipated to begin by the end of 2001.	December 2002
Manchester Airport				
Manchester Airport Access Road	Construction of a limited access highway to connect Route 3 (F.E. Everett Turnpike in New Hampshire) directly to Manchester Airport.	New Hampshire Department of Transportation	Undergoing final phase environmental review process.	2004-2005
Route 3 North Improvements	Upgrade of Route 3 from Route 128 in Burlington to the New Hampshire state line in Tyngsborough. A third travel lane will be built in each direction and shoulders will be widened.	MassHighway Department	In spring 2000, MassHighway awarded contract to design/build consortia. Multiyear construction began in October 2000.	Not earlier than 2003.
Manchester Airport Entrance Roadway	Reconfiguration of Manchester Airport main entrance to ease traffic flow in and out of the airport and connect to the Manchester Airport Access Road when completed.	Manchester Airport	Phase 1 began Summer 2000. Phase 2 is scheduled to begin in 2001. Phase 3, the final phase, is expected to be completed in 2004.	2004

The Greater Worcester Access Road Improvement Project, is expected to significantly improve access from major inter-states to the Worcester Regional Airport. The current access routes to the airport are perceived by passengers and airlines as confusing and inconvenient. By significantly improving access to the airport, The Greater Worcester Access Road Improvement Project, can positively impact airport passenger levels. The impact of the proposed project on Worcester Regional Airport passenger levels is being studied and will be reported on in MassHighway's *Greater Worcester Access Improvement Project, Draft EIS/EIR* (expected filing date is October 2001).

2.9 Initiatives in Support of Regional Transportation Options

Federal, state, and local transportation agencies are collaborating to develop and evaluate regional transportation options in New England which will ease the burden on Logan Airport. This section discusses the ways in which these agencies are achieving this shared goal. Table 2.9-1 summarizes major past and planned investments at regional airports and highlights cooperative funding efforts.

2.9.1 Agency Roles in Regional Transportation Planning

Massport

Massport is promoting the use of regional airports and travel modes to provide relief to Logan Airport. As an independent authority that owns and operates Logan Airport and Hanscom Field, operates Worcester Regional Airport, and owns and operates the Tobin Bridge as well as many properties in the Port of Boston, Massport is just one of many agencies that influence regional transportation policy. With regard to aviation, Massport's primary responsibilities are the provision, operation, and maintenance of airport infrastructure at Logan Airport and Hanscom Field, and operation of Worcester Regional Airport. On April 15, 1999, Massport entered a Memorandum of Understanding (MOU) with the City of Worcester, Massachusetts and the Worcester Airport Commission. The MOU contemplates Massport's takeover of Worcester Regional Airport in two separate phases. In January 2000, the first phase, assumption of operating responsibility, occurred. The second phase, transfer of ownership, is anticipated to be effected by separate agreement by 2005.

Table 2.9-1
Investments in the Region's Airports

Airport	Investments up to December 2000	Proposed Investments in Next Five Years
T.F. Green/Providence	***$100M FAA Funds***	***$25M FAA Funds***
	$11M Rhode Island Airport Corp.	***$18M Rhode Island Airport Corp.***
	New Passenger Terminal	***$25M Federal Rail Administration***
	New Roadways	***$5M State***
	New Parking Garage	Expand Terminal Facilities
	Airfield Improvements – Taxiway and Runway Reconstruction	Amtrak Rail Station and People Mover to Terminal Complex
	Residential and School Sound Insulation	Improved Runway Safety
		Complete Residential and School Sound Insulation
Manchester Airport	***$75M FAA Grants***	***$70M FAA***
	$7M Manchester Airport Authority	***$105M Manchester Airport Authority***
	New Passenger Terminal	***$75M Federal Highway Administration***
	New Parking Garage	Expand Terminal
	Improved Runway Instrumentation	Expand Parking Garage
	Runway Extensions (under construction)	Provide CAT III Instrumentation to Runway 35 and add ILS to Runway 24
	Residential & School Sound Insulation	Continue Sound Insulation and Property Acquisitions
		Complete Runway and Taxiway Extensions
		Access highway connection to F.E. Everett Turnpike and Route 3
Worcester Regional Airport	***$17M FAA Grants***	***$20M FAA***
	$2M City of Worcester	***$2M City of Worcester***
	New Terminal Building	***$50M Mass Highway***
	Improved Runway Safety	Airfield Enhancements
	Improved Instrumentation to reduce Weather Cancellations	Improved Runway Safety
		Greater Worcester Access Improvements
Pease International Tradeport	***$23M FAA Grants***	***$10M FAA Grants***
	$2M Pease Development Authority	***$1M Pease Development Authority***
	New Terminal Building	New Access Road/Auto Parking
	Reconstruction of Runways and Taxiways	General Airfield Improvements
	Improved Instrumentation and Approach Lighting	

Since Massport has no jurisdiction over the development, operation, or use of infrastructure at airports other than Logan, Hanscom Field, and Worcester Regional, or over the use of inter-city rail, Massport's role in regional transportation planning often focuses on cooperative planning with other airports and agencies. The following subsections discuss those agencies, other than Massport, that assume responsibility for the development and operation of other airports and inter-city rail

Federal Aviation Administration (FAA)

The FAA, an agency of the US Department of Transportation (U.S. DOT), is the principal Federal entity responsible for national aviation planning and airspace management in the United States. The FAA employs several mechanisms for supporting the planning and development of the nation's airport infrastructure: prepare the *National Plan of Integrated Airport Systems*; administer the Airport Improvement Program (AIP) Trust Fund; approve Passenger Facility Charges (PFCs); and promulgate standards and guidelines for airport design and construction. By law, the FAA cannot dictate the airports that an airline may serve; the schedules that an airline may offer; or the fares that an airline may charge. The airlines make all of these decisions according to market conditions and their respective operating strategies. However, the FAA does approve operating specifications with respect to new entrant airline services at individual airports.

Beginning with the first regional assessment for a new airport, the FAA New England Office has been an active partner in regional aviation planning in New England. The FAA has also funded all of the aviation planning efforts listed in Table 2.9-2. The FAA will play the same role in the upcoming *New England Airports System Study*. The study will evaluate the impact of recent regional airport developments on Logan Airport, identify constraints to regional airport growth, and highlight strategies for optimizing New England's regional aviation system.

The proposed draft scope of work outline for this study is presented in Table 2.9-3 (see also Appendix B). As early as 1990, the FAA began prioritizing its Airport Capital Improvement Plan (ACIP) to reflect the importance of AIP funding development at the Manchester and T.F. Green / Providence Airports in the regional system.

In conjunction with the proposed *New England Airports System Study*, the FAA, through the United States Department of Transportation's "One DOT" initiative, has formed an intermodal group that includes the Federal Highway Administration (FHWA), the Federal Transit Authority (FTA), and the Federal Rail Administration (FRA). The purpose of the intermodal group is to discuss and coordinate planning and development that can impact the Boston regional transportation system.

Table 2.9-2
New England Regional Transportation Planning Studies

Year	Study	Author	Conclusions
1989	Boston Regional Airport System Study	Massport	Scheduled service at regional airports will re-capture some passengers that were using Logan, but growth in demand at Logan will continue. High speed rail service to New York provides some relief, but there will be a need for a major second airport beyond 2010.
1990	High Speed Rail Benefits Study*	Coalition of Northeastern Governors (CONEG)	Electrification of Northeast Corridor rail would shift 2.2 million passengers from air to rail by 2010.
1991	Second Major Airport Study*	Massachusetts Aeronautics Commission (MAC)	Developing a second major airport would require a 10- to 15-year planning horizon for site selection and environmental review in addition to a multi-year construction period. While the SMA identified sites for further study, none of the sites had good access to Logan's core market area and there was significant opposition to siting a new airport anywhere in Massachusetts. Therefore construction of a second airport is not a solution for accommodating demand for the foreseeable future.
1993	Strategic Assessment Report (SAR) *	FAA and Massachusetts Aeronautics Commission (MAC)	High speed rail, development of the regional airports, and infrastructure improvements at Logan Airport are all needed to accommodate the region's growing demand for inter-city travel. The SAR recognized the importance of Runway 14/32 for reducing delays at Logan and the limitations of peak hour pricing. Further, the SAR clearly stated that peak hour pricing would impose "significant costs to travelers, commuter operators and air carriers, and the local economies of numerous cities and towns."
1995	New England Transportation Initiative (NETI)	New England Governor's Council	Coordinated planning is necessary to enhance the competitiveness of regional airports and the efficiency of the region's air transportation network. Procedural and infrastructure improvements at Logan are also necessary to mitigate increasing congestion and delay at the region's primary airport.
1995	New England Regional Airports Air Passenger Service Study*	New England Council, 6 New England States, FAA, Massport and MAC	The study identified sufficient demand at the outlying airports to support improved jet services. The study concluded that expanded jet services, particularly low-fare airline services, at the regional airports would enhance their ability to attract passengers that bypass the regional airports in favor of Logan.
2000	New England Intergovernmental Coordinating Council	Council of New England Governors	The first ICC meeting was held in February 2001. The Council is establishing committees to examine opportunities for inter-modal connections and to recommend interstate transportation initiatives. The ICC members are the six state transportation secretaries, Massport and the regional airport directors.
2001	New England Airports System Study Update*	New England Council, 6 New England States, FAA, Massport and MAC	The *New England Airports System Study* will evaluate the impact of recent regional airport developments on Logan Airport, identify constraints to regional airport growth, and highlight strategies for optimizing New England's regional aviation system. See Table 2.9-3 for the proposed scope of the study update.

* Partial funding provided by Massport.

Table 2.9-3
New England Airport System Study Proposed Scope of Work

Phase	Tasks	Products
I	■ Regional Aviation Forecasting ■ Studies to Facilitate a Possible Reshaping of the Market	■ New Regional Passenger and Cargo Forecasts ■ Updated Passenger and Fleet Forecasts ■ Identification of Updated Catchment Areas ■ Identification of New Service Market Opportunities
II	■ Evaluation of Major Public Policies, Alternate Airline Strategies, Federal Aviation Policies and Regulations that Guide Regional Systems Planning ■ Evaluation of Federal Aviation Policies or Regulations that Restrict Cooperative Intermodal System Planning ■ Public Policy Development and Action Recommendations	■ Implementation Plan/Program of Major Actions Required to Support a Regional Strategy to Enhance Air Passenger Service ■ Ongoing Planning and Evaluation Capability to Guide Evolution of Regional Strategy
I and II	Ongoing Public and Agency Consultation with Congressional, Business, Environmental and Community Groups	

State Aviation Authorities and Departments of Transportation

State entities involved in aviation planning in New England include statewide aviation authorities and transportation departments. In Massachusetts, the Executive Office of Transportation and Construction (EOTC) coordinates statewide transportation planning and compiles the Statewide Transportation Improvement Program (STIP). The Massachusetts Aeronautics Commission (MAC) performs licensing and reviews activities at all civil airports in the state, except for Logan Airport and Hanscom Field, which fall under Massport's jurisdiction. The MAC was also the lead agency for the *State Airport System Plan, The Second Major Airport Study*, and the *Strategic Assessment Report*. In addition, MAC was a co-sponsor, along with Massport, for the *New England Regional Airports Air Service Study*.

The New England state aviation directors and departments of transportation formed a unique alliance with the FAA, Massport and regional airport authorities to study regional airports in 1994. This alliance produced *the New England Regional Airports Air Passenger Service Study* in 1995.

Local Airport Proprietors

At the local level, airport authorities, commissions and municipal departments own and operate civil airports. Local airport proprietors supply, operate, and maintain airport infrastructure, which includes the runways, taxiways, terminal facilities, parking facilities, and access roads. The airport proprietor plays no role in the decisions of private airlines

regarding airfares, airline routes or service levels, but routinely engages in marketing activities to foster air service development.

Federal Railroad Administration (FRA)

The FRA is the Federal agency within the U.S. DOT that plans and funds inter-city railroad projects. The agency promotes safe, environmentally sound and effective rail transportation in the United States. The FRA was the principal funding source for the recently-completed Northeast Corridor Improvement Project (NECIP), which allows high-speed train travel between Boston and New York.

Federal Highway Administration (FHWA)

The FHWA is the federal agency within the U.S. DOT that provides expertise, resources, and information to continually improve the quality of the nation's highway system and its intermodal connections. These goals are accomplished through two main FHWA programs. The Federal-Aid Highway Program provides federal funds to the States for new construction and improvements to the National Highway System, urban and rural roads, and bridges. The Federal Lands Highway Program provides access to and within public lands, such as national forests, by preparing plans, letting contracts, supervising construction, and conducting bridge inspections and surveys. The FHWA also conducts and manages a comprehensive research, development, and technology program to support the nation's highway system.

2.9.2 Regional Transportation Planning and Development in New England

The proposed Airside Project improvements at Logan are an important component of a broader regional transportation strategy that has been evolving for more than a decade. A series of regional transportation planning studies beginning in 1989 examined various strategies and modes for accommodating the growing demand for inter-city travel and for relieving congestion and delays at Logan Airport. Each study built upon the conclusions of prior studies and included participation from a range of transportation interests and agencies.

The key regional planning efforts and their principal conclusions, which were described in Section 2.2.1 of the Logan Airside Improvements Planning Project Draft EIS/EIR, are summarized below and in Table 2.9-2.

These regional transportation planning studies have consistently recommended the development of High Speed Rail in the Northeast Corridor, a growing role for the regional airports, and infrastructure improvements at Logan as essential elements of a regional transportation strategy. The recommendations and goals put forth by these regional planning efforts are now being achieved in New England.

- Low-fare airlines, notably Southwest Airlines, Delta Express, and MetroJet, as well as other major United States airlines, have substantially expanded jet services at the T.F. Green / Providence and Manchester airports. As a result, these airports have increased their roles in accommodating the region's air travel demand and are providing considerable traffic relief for Logan Airport, particularly for passengers originating from points to the north and south of Logan's core service area.

- The electrification of the northern portion of the northeast corridor rail has been completed and Amtrak's high speed Acela service was initiated in December 2000. This service will provide relief to Logan by accommodating some of the inter-city air passenger demand in the Boston-New York market, which is Logan Airport's largest origin-destination market.

- An intermodal station being developed at T.F. Green Airport in Warwick, RI will provide a commuter rail link from Boston's South Station and the Route 128 Station to the Warwick, RI Station with people mover access to T.F. Green Airport. This access improvement will allow more residents of the Boston Metropolitan Area to utilize T.F. Green's frequent, low-fare air services.

- Substantial infrastructure improvements at the regional airports have been completed and others are in various stages of planning or construction.

  - Since 1996, investments made at T.F. Green Airport include a $207-million terminal building and seven additional aircraft gates. In 1999, investments included a $1.5-million expansion with a new Federal Inspection Facility (FIS) and parking facilities.

  - The Manchester Airport is involved in a 9-year, $260 million capital improvement project. The project includes reconstruction and lengthening of both runways; an ILS upgrade; taxiway work; expansion of the terminal building; a parking garage; and a new roadway entrance. The New Hampshire Department of Transportation is also planning a $75 million highway that will connect the airport to the F.E. Everett Turnpike. Construction of the roadway is expected to begin after 2000.

  - The Massachusetts Highway Department (MassHighway) is studying alternatives for an east-west connector road that would improve access to and within the City of Worcester and to the Worcester Airport. MassHighway filed the Greater Worcester Access Road Project Environmental Notification Form (ENF) at the end of 1999. In February 2000, the Secretary of the Executive Office of Environmental Affairs (EOEA) issued a decision on the ENF requiring an EIR. A combined Draft EIS / EIR is expected to be filed in October 2001.

- In January 2000, Massport assumed operational control of Worcester Regional Airport to increase its utilization and provide relief to Logan for traffic originating in Central Massachusetts and the MetroWest suburbs.

- Massport continues to invest in Logan Airport, which will remain the region's principal airport. It is completing landside improvements and is proposing Airside Project improvements that will allow Logan to operate more safely, reliably and efficiently, resulting in less congestion and delay.

2.9.3 Massport's Initiatives in Support of Regional Alternatives

Massport advocates a regional transportation policy to improve the efficient use of the region's transportation infrastructure by appropriate expanded use of regional airports and alternative transportation modes. To achieve this policy goal, Massport is committed to cooperative transportation planning and is actively working with a broad array of transportation agencies and concerned parties to ensure an integrated, multi-modal regional transportation network. Massport has undertaken several initiatives to advance the role of regional airports in accommodating a greater share of the region's air travel demand. Massport is also participating in several interagency transportation planning forums pertaining to alternative, inter-city travel modes. The *1996, 1997,* and *1998 Annual Updates* and the *1999 Environmental Status and Planning Report* (formerly the GEIR) describe some of these past initiatives and cooperative planning ventures. The following subsections describe Massport's more recent initiatives.

Massport Involvement in Cooperative Planning Initiatives

- Massport continues to maintain an aviation information database and distributes quarterly summary reports that track aviation trends at all of the regional airports to parties interested in promoting regional airport services. Massport compiles and issues monthly statistical summaries of passenger levels, aircraft operation counts and airline schedule data at each regional airport. At the end of each year, Massport also prepares an annual report summarizing regional airport trends and service developments.

- Massport participates in meetings of other regional and state aviation organizations and the MAC. Topics discussed at these meetings include airfield and terminal improvements at state airports; capital improvements at New Bedford, Martha's Vineyard, and Nantucket; and the Worcester Marketing Program.

- In January 1999, the Transportation Research Board (TRB) invited the FAA, Massport and MAC to present their collaborative regional planning efforts as a national model for regional aviation system planning.

- On November 23, 1999, Massport participated in a "Regional Transportation Summit" that it sponsored with the Cellucci / Swift Administration. This summit enjoined New England governors, transportation officials, and business leaders to discuss joint transportation initiatives in New England. The agenda included a panel discussion on aviation, which focused on joint marketing initiatives among the major commercial airports in New England and the economic value of airports to the New England economy. At the close of the Summit, state leaders agreed to the following action steps:

  - Encourage the Massachusetts legislature to pass the Transportation Bond Bill to increase rail service to Providence. This legislation was passed, and through the Pilgrim Partnership formed between the MBTA and Rhode Island, in July 2000, three additional commuter rail trains were added between Boston's South Station and Providence. The additional rail services, coupled with the link that is under-construction to the T.F. Green / Providence Airport will increase transit options for Boston passengers seeking use of theT.F. Green / Providence airport.

  - Create a joint marketing program to promote the region's airports to air passengers inside and outside New England. The program includes detailed brochures that display the region's airports, their airlines, and major access routes. The program also involves participation in industry trade shows to promote the regional airports. A joint web site, *flynewengland.com*, linked with the various airport and state aviation home pages, and with travel and tourism sites, has been developed.

  - Establish a comprehensive rail plan for all of New England to integrate each state's assets and needs into one regional strategy. Since the Summit, the Executive Office of Transportation and Construction has partnered with New Hampshire to develop commuter rail from Lowell, MA to Nashua, NH. Furthermore, Massachusetts has joined other New England states to ask the Federal Rail Administration to designate two high-speed, rail corridors. In March 1999, Massachusetts, Maine, and New Hampshire jointly filed applications for a Portland-Boston designation. In August 2000, Massachusetts, Vermont, and New Hampshire jointly filed an application for a Boston-Montreal designation. Federal transportation officials approved both of these applications in October 2000, making the participating states eligible to apply for Federal money to fund safety and capacity improvements on higher-speed rail lines.

  - Meet annually to discuss regional transportation issues and accomplish regional goals to improve infrastructure development, use, and efficiency.

- In December 1999, Massport met with MassHighway and MAC to develop the Regional Airport Signage Program. MassHighway developed signs to direct Massachusetts residents to the Manchester, T.F. Green / Providence and

Bradley / Hartford airports, and installed them in February 2000. MAC provided $20,600 in funding for the signage program.

- Massport spent $80,000 on a print advertising program to promote regional airports. The program ran advertisements in newspapers west of I-495 and near the Connecticut, New Hampshire, and Rhode Island borders to promote the advantages of regional airports over the traffic and congestion at Logan Airport.

- In 2000, Massport, the FAA and the regional airport directors agreed to jointly undertake a *New England Airports System Study*. This study will evaluate the performance of the regional airports since the completion of the 1995 Regional Airports Air Passenger Service Study. It will re-evaluate airport market areas and capture rates in light of the significant air service changes that have occurred in the last few years; evaluate the potential for international, charter, and cargo services at the regional airports; evaluate capacity issues at each of the airports; and consider the development of high occupancy vehicle / ground transportation and rail alternatives to improve access to the regional airports. (See Table 2.9-3 and Appendix B).

- In January 2001, Massport committed $500,000 to a regional marketing plan, to encourage air travelers to fly out of regional airports, when possible, instead of Logan. The marketing campaign will consist of TV ads, printed materials, and industry trade shows to promote the regional airports.

- On February 16, 2001, Massport participated in the first meeting of the New England Intergovernmental Coordinating Council Meeting.

Worcester Regional Airport: Marketing and Planning Initiatives

Since 1995, Massport has been working with the City of Worcester to develop strategies to realize its airport's full potential, thereby improving the New England air transportation network. Recent efforts are summarized below.

- In accordance with an Operating Agreement with the City of Worcester and the Worcester Airport Commission, Massport assumed operational responsibility for Worcester Regional Airport on January 15, 2000.

- Massport has secured new nonstop services at Worcester Regional Airport:

  - In February 2000, Atlantic Southeast Airlines, a regional carrier subsidiary of Delta Air Lines, began serving Worcester Regional Airport market with two daily flights to Atlanta, with 50-seat Canadair Regional Jets. This service has been highly successful. During the first four months of service, load factors reached 73 percent, climbing to 94 percent in August 2000. Delta will increase its Worcester-Atlanta service to three daily roundtrips in April 2001.

- In July 2000, American Eagle initiated nonstop flights to New York JFK International Airport. The service is operated three times per day, with 34-seat Saab 340 turboprops.

- In February 2001, Pan Am began daily nonstop jet service to Orlando Sanford International Airport.

- Massport has embarked on an aggressive marketing campaign targeted to travelers and the airlines:

  - Massport launched an advertising campaign promoting the headline "Even Worcester Airport has delays ...five minutes to park, two minutes to check in." The campaign targets travelers within 25 miles of the airport and builds awareness of its new air services and convenience. The campaign runs advertisements in area cinemas and local newspapers, and on local radio stations. Additionally, Massport hired a full-time marketing manager to promote the airport to airlines, travel agents, local businesses, and residents.

  - Massport is engaged in a strategic marketing plan to attract airlines that could provide services at Worcester Regional Airport. To date, Massport presented air service proposals to Spirit Airlines, Jet Blue, American Trans Air, American Airlines, Delta Air Lines, Continental Airlines, Shuttle America, and Pan Am. Other airlines are also being targeted for new services at Worcester Regional Airport.

Other Cooperative Regional Transportation Planning Efforts

- Massport supports inter-city rail planning through its membership in the Boston Metropolitan Planning Organization (MPO). The MPO is a cooperative planning board that consists of these other state and regional agencies: EOTC; MassHighway; Metropolitan Area Planning Council (MAPC); MBTA; and the MBTA Advisory Board. Massport and the other MPO agencies prepared the *Transportation Plan for the Boston Region* and *the Boston Transportation Improvement Program (TIP).*

- Rhode Island Governor Lincoln Almond hosted the second annual New England Regional Transportation Summit on December 14, 2000. Joining Governor Almond was Massachusetts Governor Cellucci, Connecticut Governor John Rowland, and Massport officials. The Governors cited aviation, truck transportation and the movement of more goods by rail as their top transportation priorities, and resolved to re-establish the New England Governors Conference Committee on Transportation as a regular forum for discussing regional transportation initiatives. (See Appendix B for the New England Governors' Resolution.)

2.10 Conclusion

New England's demand for high-speed intercity travel, particularly air travel, has increased over time and will continue to increase in the future. This poses significant challenges for the region which is increasingly congested on its roads and interstate highways, and at Logan, its principal airport. Major investments and innovative solutions are needed to accommodate future travel demand efficiently and with minimal congestion. Reducing travel delays provides widespread regional benefits by eliminating wasted time, promoting stable economic growth, and minimizing negative environmental impacts.

Local, state and federal agencies throughout the region share the goal of improving New England's transportation network and have already begun to work, both independently and cooperatively, to achieve that goal. Great strides have been made in the last decade. Regional airports have become meaningful options to Logan Airport and passengers traveling to and from New York can now choose high-speed rail over air travel.

These are significant achievements that resulted from years of planning efforts involving many different agencies. Local airport authorities and the FAA were responsible for significant infrastructure investments at the region's airports. Through individual and cooperative efforts, the regional airports have attracted meaningful airline services and have increased their share of the region's travel demand. Massport has assumed operating responsibility for the Worcester Regional Airport, which is capable of handling more of the region's air travel. In just one year, Massport obtained new air services for the airport which resulted in a two-fold increase in Worcester's passenger traffic. State governments have undertaken a number of road and commuter rail projects to improve access throughout the region and make regional airports more accessible. The Federal Rail Administration and Amtrak have implemented high-speed rail along the Northeast Corridor, the only active high-speed rail service in the nation.

While these are meaningful accomplishments, the process for ensuring a balanced, integrated and efficient regional transportation system is on-going. The states are evaluating additional opportunities for high-speed rail services in New England. The FAA and Massport are sponsoring a *New England Airports System Study* to identify new opportunities for growth at the regional airports and other innovative initiatives. Massport is spearheading a cooperative marketing campaign to attract more passengers to the regional airports. Massachusetts and Rhode Island are cooperating to bring rail access to the T.F. Green / Providence Airport. All agencies are doing their part to ensure that the region meets its long-term transportation objective.

Many of the region's transportation projects and planning efforts are directed at creating and expanding transportation options to Logan Airport. Experience shows that increasing the role of regional airports reduces the rate of passenger growth at Logan by distributing air passenger growth across the region. Yet, Logan plays a critical role in the

regional transportation network. It is closest to the majority of the region's travel demand and the only airport in New England that can serve the long-haul domestic and international travel needs of the region. Even with regional airports and rail improvements, Logan will continue to be a vital part of the regional transportation network and its passenger levels will continue to grow. From a regional system planning perspective, it is imperative that Massport improve the efficiency of Logan Airport, since Logan serves the greatest number of passengers and there is no other airport or group of airports that could fulfill the role that Logan plays as the primary airport for the region within I-495 and the region's gateway for nonstop services to long-haul domestic and international destinations.

Massport's Logan Modernization Program, which will be completed in the coming decade, is improving the airport roadway network and upgrading the airport's landside facilities. The proposed Airside projects are also needed to improve the efficiency and reliability of Logan's airside operations.

Despite past and planned efforts to improve regional transportation options, Runway 14/32 is the only measure that can eliminate Logan delays that occur during northwest wind conditions. If Runway 14/32 is not built, the majority of the region's air travelers will continue to suffer from unreliable and inefficient air travel at Logan Airport.

3 Alternatives

Key Points

In the *Airside Improvements Planning Project Draft Environmental Impact Statement/ Environmental Impact Report* (Airside Project Draft EIS/EIR), Chapter 3 provided a detailed description of the improvement concepts. In this Supplemental DEIS/FEIR, these alternatives are reviewed again, but in more summary form. In addition, this chapter discusses demand management strategies at US and international airports, including previous Massport efforts at Logan, for relevance to the current Peak Period Pricing concept.

- The following improvement concepts designed to reduce congestion and delays and enhance safety at Logan Airport were evaluated in the Airside Project Draft EIS/EIR prior to selection of the Preferred Alternative:
  - **Unidirectional Runway 14/32** was designed to address delays during northwest winds and to provide a third active runway during conditions that now require Logan to operate on two or fewer runways. All arriving and departing flights using Runway 14/32 would occur over Boston Harbor. This additional three-runway configuration with proposed unidirectional Runway 14/32 would enable better conformance with the PRAS runway use goals designed to more equitably distribute noise impacts among affected communities.
  - **Taxiway improvements** were designed to reduce taxiway congestion and enhance safety, facilitating more efficient movement of aircraft between terminal areas and runways during takeoff and landing operations. By reducing congestion and simplifying the taxiway system, the taxiway improvements will reduce the potential for runway incursions and wingtip conflicts.
  - **Reduced approach minimums** for Runways 15R, 22L, 27 and 33L will increase the availability of these runways, reducing reliance on Runway 4R in low visibility and enhancing safety under adverse operating conditions. The Runway 22L and Runway 27 minimums will be reduced to levels consistent with the capabilities of the existing navigational equipment, while approaches to Runways 15R and 33L will be upgraded to Category III Instrument Landing Systems (ILSs). Reduced minimums will also increase the opportunity to achieve short- and long-term Preferential Runway Advisory System (PRAS) goals.
  - **Peak Period Pricing** designed to reduce delay by eliminating flights during periods when demand exceeds the airfield's capacity for a sustained period of time.

- A runway length (exclusive of safety areas) of 5,000 feet was selected for unidirectional Runway 14/32 based on the finding that this runway length would accommodate a greater proportion of the regional carrier fleet than the alternative 4,500 foot length and therefore was more effective in reducing delay.[1]

- An illustrative peak period fee of $150 per operation was selected in a screening process, based on the finding that this fee would be effective in reducing delay in a future High Fleet scenario with airline overscheduling during the peak hours.[2]

- The alternatives evaluated consist of the following combinations of improvement concepts:

  - Alternative 1 – All improvement concepts
  - Alternative 1A – Preferred Alternative -- All improvement concepts, except Peak Period Pricing
  - Alternative 2 – All improvements concepts, except Runway 14/32
  - Alternative 3 – No Build, operational improvements and Peak Period Pricing only
  - Alternative 4 – No Action

- Alternative 1A was selected as the Preferred Alternative because it significantly reduces delays without imposing the economic costs on regional carriers and small communities associated with Peak Period Pricing. The Preferred Alternative achieves certain environmental benefits that include improved air quality and a reduction in noise for the most severely impacted communities, while causing minimal environmental impacts that would be mitigated.

- As discussed in Chapter 2, regional alternatives (including development of the regional airports and high speed rail services) will play an important role in the emerging regional transportation system by diverting from Logan a portion of its short- and medium-haul demand. Logan, however, will remain the region's major airport for long-haul domestic and international travel and continue to serve as a primary point of access to the national air transportation system for passengers from small- and medium-sized New England communities. The proposed airfield improvements for reducing delay are necessary for Logan to operate reliably and efficiently in the regionalized transportation system.

In response to the Secretary of the Executive Office of Environmental Affairs (EOEA) Certificate on the Airside Project Draft EIS/EIR (May 7, 1999), additional analyses were performed to assess the impact of previous differential pricing programs at Logan. While it was not a Peak Period Pricing program, Logan's 1988 Program for Airfield Capacity Efficiency (PACE) increased landing fees for operators of small aircraft, including

▼

1 A runway longer than 5,000 feet was analyzed earlier. It would require construction into the harbor and was therefore considered impractical.

2 The fleet forecasts include High Fleet and Low Fleet operations scenarios for each passenger level. The Low Fleet scenarios assume more large jet operations than non-jet operations, similar to current conditions, while the High Fleet scenarios assume a greater proportion of smaller non-jet aircraft and thus a higher level of total operations for the same passenger level. The higher number of small aircraft in the High Fleet scenarios reflects airline overscheduling conditions.

regional carriers and general aviation. During the six-month period when PACE was in effect, flight activity levels within these segments did decline, but it would be incorrect to attribute these changes to PACE alone. A review of factors influencing Logan flight activity during this period indicates that consolidation within the regional carrier industry and a general downturn in general aviation demand may have had equal or greater responsibility for the observed changes.

3.1 Introduction

A range of Logan-specific alternatives to reduce congestion and delay and enhance safety at Logan have been considered in the Logan Airside Improvements Planning Project (Airside Project). Phase I of the project was initiated in 1993 as a feasibility study that examined the nature of delays at Logan and evaluated the potential delay savings and safety enhancements for a range of individual improvement concepts.[3] The concepts evaluated in the Phase I study evolved from alternatives considered in previous studies, most notably the FAA's *Boston Logan International Airport Capacity Enhancement Plan (CEP),* published in October 1992. Additional sources for the concepts included the *Logan Runway Incursion Mitigation Plan/ Taxiway Relocation Study* (December 1993), and recommendations by Massport staff, airlines, and the Air Transport Association (ATA).

Based on the results of the *Phase I Feasibility Study*, the Massport Board in July 1995, selected seven improvement concepts for more detailed operational and environmental analysis through a joint federal and state EIS/EIR. These concepts were presented in the Environmental Notification Form (ENF) for the Airside Project and further developed during the federal and state EIS/EIR scoping process. Consistent with the scope issued by the EOEA and the January 1996 EIS Scope issued by the FAA, the Airside Project Draft EIS/EIR assessed the following improvement concepts:

- Construction of a unidirectional Runway 14/32;
- Construction of a Centerfield Taxiway;
- Extension of Taxiway Delta;
- Realignment of Taxiway November;
- Optimization of taxiways in the Southwest Corner of the airfield;
- Reduction in approach minimums on Runways 22L, 27, 15R, and 33L; and,
- Implementation of Peak Period Pricing.

3 Logan Airside Project improvements Feasibility Study, Phase I Report, prepared by Jason M. Cortell and Associates Inc. for the Massachusetts Port Authority, July 20, 1995.

The analytical framework was structured to evaluate five distinct packages of improvement concepts, or Alternatives. Alternative 1 includes the full package of feasible improvements (see Figure 3.1-1) and Alternative 1A includes all improvement options except for Peak Period Pricing. Alternative 2 includes all actions except the construction of Runway 14/32 (see Figure 3.1-2). Alternative 3 is a No Build Alternative, employing only the operational and administrative improvement concepts (reduced minimums and Peak Period Pricing). For comparison, Alternative 4 is a No Action Alternative, evaluating the impacts of doing nothing (see Table 3.1-1).

Sections 3.2 through 3.5 discuss each individual improvement concept, and its role in reducing current and projected levels of congestion and delay at Logan. An expanded description of the Alternatives is included in Section 3.6.

The comparative benefits and impacts of the different Alternatives were fully described in Chapters 4 and 8 of the Airside Project Draft EIS/EIR.

After careful review of the extent and causes of delays at Logan and the comparative benefits of each Alternative, FAA and Massport selected Alternative 1A as the Preferred Alternative because it significantly reduces delays without imposing the economic costs on regional carriers and small communities associated with Peak Period Pricing. Peak Period Pricing was not selected because an overscheduling condition does not exist at Logan today.

Alternative 1A achieves certain environmental benefits that include improved air quality and a reduction in noise for the most severely impacted communities, while causing minimal environmental impacts. These minimal impacts would be mitigated as described in Chapter 8.

3.2 Unidirectional Runway 14/32

This section describes proposed unidirectional Runway 14/32 (illustrated in Figure 3.1-1), including the purpose of this improvement, the process used to screen various runway lengths and layouts, a physical description of the preferred layout, and a brief assessment of technical and environmental issues associated with it.

Unidirectional Runway 14/32 would be located along the southwestern edge of the airport. All arrivals would be from the southeast over Boston Harbor and would touch down at the Runway 32 end and taxi toward the Runway 14 end. All departures would leave from the Runway 14 end, with jets climbing out and heading southeast over the harbor.

Runway 14/32 would address delays at Logan that occur when wind and weather (particularly moderate to strong northwest winds) limit Logan to two-runway configurations and sometimes to single-runway configurations, a major cause of delay. With three runways in visual flight rule (VFR) weather conditions, Logan's capacity is approximately 120 operations per hour. Two runways can accommodate up to 90 hourly operations and a single runway provides 60 or fewer hourly operations. The high proportion of smaller, regional aircraft in the fleet at Logan also contributes to delay, because the separation distances required between larger and smaller aircraft using the same runway are often greater than between two aircraft of the same size. When greater separation distances are required, the time needed to complete each aircraft operation (e.g., landing or takeoff) increases, which can result in additional delay for subsequent operations. Along with the taxiway improvements, the new runway would also enhance operational safety at Logan (e.g., separating large and small aircraft operations, and reducing the potential for runway incursions or wingtip conflicts) by reducing congestion in the air and on the ground.

In addition, Runway 14/32 would provide the FAA with greater flexibility to shift operations among the different primary operating directions in order to be more consistent with the runway use goals embodied in the Preferential Runway Advisory System (PRAS) at Logan. PRAS attempts to reduce the areas subject to the highest noise exposure levels, distribute noise impacts evenly in the long term, limit sustained impacts in the short term by regularly shifting operations when possible, and maximize use of over-the-water procedures.[4] By providing capacities similar to those available in the north/south configurations, Runway 14/32 would allow a more equitable distribution of jet operations.

3.2.1 Runway Length Screening

An initial screening analysis was carried out in the Airside Project Draft EIS/EIR to determine the Runway 14/32 length to be carried through the detailed operational and environmental analysis process. Alternative runway lengths for a unidirectional Runway 14/32 were screened for their ability to reduce delay, to conform to the PRAS

4 PRAS is described in more detail in Chapter 4, Section 4.3.

goals, and to reduce noise impacts. The purpose of the screening process was to identify the feasible runway length that best achieves these objectives.

The proposed unidirectional Runway 14/32 is intended principally to serve the regional/commuter airlines, which typically operate turboprops and small jets. Therefore, the screening process examined runway lengths (exclusive of safety areas) of 4,500 and 5,000 feet.[5] A discussion of the screening process and results can be found in Section 3.2.1 of the Airside Project Draft EIS/EIR.

Because a 5,000-foot runway would accommodate a greater proportion of the forecast regional carrier fleet than a 4,500-foot runway, it would provide a greater reduction in aircraft delay, as illustrated in Table 3.2-1. Although the effect of each runway on the achievement of the PRAS goals and on noise impacts varies somewhat depending upon whether the 37.5M Low or 45M High Fleet scenarios are employed, the overall improvements in both criteria favor the 5,000-foot runway.[6] Therefore, the 5,000-foot runway was selected for further analysis in the Airside Draft EIS/EIR.

Table 3.2-1
Summary Comparison of the Impact of Runway Length on Aircraft Delay

	Runway 14/32 Length	
	4,500 feet	**5,000 feet**
Percent of Forecast Regional Carrier Fleet Able to Land on Runway 32 or Depart From Runway 14		
Low Fleet Scenario (37.5 million passengers)	69%	98%
High Fleet Scenario (45 million passengers)	68%	98%
Percent Reduction in Aircraft Delay		
Low Fleet Scenario (37.5 million passengers)	20%	22%
High Fleet Scenario (45 million passengers)	26%	33%

Runway 14/32 at either length would improve conformance to the PRAS goals, designed to equitably distribute noise among impacted communities, but 5,000 feet is the preferred runway length based on both the long- and short-term PRAS goals. Because the 5,000-foot runway would accommodate a greater variety of aircraft, it would provide better performance relative to the annual goals than the 4,500-foot runway. It would also produce a greater reduction in the total annual hours of persistence exceedence.[7] The performance of the two runway lengths varies by fleet scenario with respect to the PRAS dwell criteria,[8] but the differences are very small.

5 A runway longer than 5,000 feet was analyzed earlier. It would require construction into the harbor and was therefore considered impractical.
6 The screening analysis used the 37.5 million passenger Low Fleet and the 45 million passenger High Fleet. The Low Fleet scenarios assumes a high proportion of large jet operations, similar to current conditions, while the High Fleet scenario assumes a greater proportion of smaller non-jet aircraft.
7 Persistence is defined as the prolonged utilization of one runway combination between the hours of 7:00 AM and midnight in a period of three consecutive days.
8 Dwell is defined as the duration of continuous operations during each day between the hours of 7:00 AM and midnight.

Noise analysis of both runway lengths yielded similar results; generally the 5,000-foot runway produced greater improvements. For the average Day-Night Sound Level (DNL) 65 decibel (dB) and greater criteria, the effect on noise impacts varied by fleet. Population levels exposed to the average day-night noise levels of 70 dB or greater are smaller for the 5,000-foot runway than for the 4,500-foot version under each fleet scenario. For the 75 dB or greater day-night noise level, the 5,000-foot runway exposes a lower population under the 45M High Fleet scenario, while the two runway lengths are equivalent under the 37.5M Low Fleet scenario.

The proposed 5000-foot unidirectional Runway 14/32 is expected to result in a certain fleet utilization percentage, and it is this utilization that drives the environmental impacts of the runway. The initial screening for runway length anticipated a regional fleet dominated by turboprop aircraft, where a 5,000 foot runway was clearly adequate to accommodate all existing and anticipated turboprop aircraft. The emergence of the regional jet called into question the adequacy of a 5,000 foot runway, and resulted in additional analysis using the 37.5M High RJ Fleet in this Supplemental Draft EIS/Final EIR.

According to the airframe manufacturers' specifications and the FAA type certifications, the regional jet types in the Logan fleet are able to land in less than 5,000 feet under standard conditions.[9] However, the conditions of each flight operation are different. Based on discussions with airlines and airports and the FAA consultant's analysis included in Appendix C, most of the regional jet types forecast to use Logan in the future are capable of landing on a 5,000 foot runway.

The analysis of the runway with the 37.5M High RJ Fleet considers a range of utilization assumptions for specific regional jet aircraft (see Section 4.7.5). Therefore, this Supplemental DEIS/FEIR analyzes the full range of environmental impacts generated by aircraft likely to use Runway 14/32, whether derived from a fleet with a large percentage of turboprop aircraft or from a fleet dominated by regional jets.

3.2.2 Layout Options

FAA-specified runway design criteria and standards were applied to develop three layout options for a 5,000-foot unidirectional Runway 14/32. Descriptions of the applicable FAA criteria and standards are presented below, followed by a physical description of the runway, presentation of the layout options and the results of a qualitative assessment of the three options. Detailed descriptions of the criteria, the runway, the layout options and the assessment procedures are provided in Sections 3.2.2.1 through 3.2.2.4, respectively, of the Airside Project Draft EIS/EIR.

3.2.2.1 FAA Runway Design Criteria and Standards

The FAA has issued Advisory Circulars (AC) governing the layout and design of runways, taxiways and associated safety areas. These Advisory Circulars generally fall within the AC 150/5300 Series.

9 Standard conditions in this case include landing over a 50-foot obstacle when the aircraft is at maximum gross weight, the runway is dry, there is no wind, and the temperature is below 60 degrees Fahrenheit.

FAA Advisory Circular 150/5300-13 Airport Design

The key Advisory Circular is AC 150/5300-13 *Airport Design*, which specifies minimum design and layout standards to be utilized at all airports receiving FAA funding. Runway design requires the identification of a design aircraft category and the lowest designated or planned approach visibility minimums, and then application of the appropriate criteria contained in *Airport Design*. In the Airside Project Draft EIS/EIR, an Airport Reference Code (ARC) of C-III was designated for Runway 14/32, based on the aircraft approach speed and airplane wingspan to be accommodated. The category of aircraft upon which this design is based is regional jets.

The design parameters for Runway 14/32 and an ARC of C-III are defined below and summarized in Table 3.2-2.

- **Runway Safety Area (RSA).** The RSA is a defined surface surrounding the runway that is suitable for reducing the risk of damage to airplanes in the event of an undershoot, overshoot, or excursion from the runway. For Runway 14/32, the RSA is 500 feet wide centered on the runway centerline, and extends 1,000 feet beyond each end of the runway. *Airport Design* requires that the RSA be cleared and graded and have no potentially hazardous surface variations. The RSA shall be free of all objects, unless required for controlling and directing aircraft. The grading shall prevent the accumulation or ponding of water within the RSA, and under dry conditions, the ground within the RSA shall be capable of supporting the occasional passage of an aircraft or aircraft rescue and fire fighting equipment without causing any damage to the equipment or aircraft.

- **Runway Object Free Area (ROFA).** The ROFA is an area on the ground centered on a runway centerline. It is provided to enhance the safety of aircraft operations by having the area free of objects, except for those needed for air navigation or aircraft for ground maneuvering purposes. The ROFA for proposed Runway 14/32 is 800 feet wide, centered on the runway centerline, and extends 1,000 feet beyond each of the runway ends, similar to the RSA.

- **Runway Protection Zone (RPZ).** FAA defines the RPZ as "an area off the runway end to enhance the protection of people and property on the ground." The RPZ is a trapezoidal area, starting 200 feet beyond the threshold of the operational runway and centered on an imaginary extension of the runway centerline for arrivals and departures. Since operations will only occur to or from the Runway 32 end of unidirectional Runway 14/32, the RPZ applies only to the Runway 32 end. The dimensions of RPZs vary depending upon the visibility minimum and the ARC code for the design aircraft. For the Runway 32 end, the length of the RPZ is 1,700 feet with an inner width of 1,000 feet and an outer width of 1,510 feet.[10]

10 FAA Advisory Circular 150/5300-13, Chapter 2, Table 2-4.

Table 3.2-2
Design Criteria for Runway 14/32 with an Airport Reference Code of C-III

Item	Design Criteria (feet)
Runway Width	100
Runway Shoulder Width	35[1]
Runway Safety Area Width	500
Runway Safety Area Length Beyond Runway End	1,000
Runway Obstacle Free Zone Length Beyond Runway End and Width	200
Runway Obstacle Free Zone Width	400
Runway Object Free Area Width	800
Runway Object Free Area Length Beyond Runway End	1,000
Taxiway Safety Area Width	118
Taxiway Object Free Area Width	186
Runway Protection Zone	Length 1,700 / Inner Width 1,000 / Outer Width 1,510

1 Massport extends the 20-foot FAA minimum runway shoulder width to 35 feet for additional safety and operational benefits.
Source: Tables 3-3 and 4-1 in FAA AC 150/5300-13 *Airport Design,* November 10, 1994.

- **Obstacle Free Zone (OFZ).** The OFZ is the airspace along the runway and extended runway centerline, which is required to be clear of all objects, (except for frangible visual navigational aids (NAVAIDs), which need to be located in the OFZ because of their function). The purpose of the OFZ is to provide clearance protection for aircraft landing or taking off from the runway and for missed approaches. The OFZ is defined as a three-dimensional surface centered above the runway centerline and extending 200 feet beyond each end of the runway. The height of the OFZ is defined as 150 feet above the established airport elevation. The width of the OFZ varies with aircraft and visibility minimums for the runway. For the proposed Runway 14/32, the OFZ is 400 feet wide centered on the runway.

- **Taxiway Safety Area (TSA).** The TSA is a defined surface alongside the taxiway prepared or suitable for reducing the risk of damage to an airplane unintentionally departing the taxiway. The TSA for a C-III taxiway is 118 feet wide centered on the taxiway centerline.

- **Taxiway Object Free Area (TOFA).** The TOFA has controlling criteria similar to that of the ROFA described above. For the proposed Runway 14/32, the TOFA is 186 feet wide centered on the taxiway centerline.

FAR 14 CFR Part 77 Objects Affecting Navigable Airspace

A second listing of key design criteria is contained within the body of the Federal Aviation Regulations (FAR) at 14 CFR Part 77. These criteria, under the heading "Objects Affecting Navigable Airspace," address the goals of safe and efficient use of airspace, and define limits around a runway in which objects are considered to interfere with the safe use of the runway.

FAR Part 77 criteria address the protection of the airspace around a given runway. The phrase "FAR Part 77 surfaces" is frequently used in reference to the several "imaginary surfaces" surrounding a runway, which are used to depict the protected airspace and are defined by the technical criteria of FAR Part 77. The basic purpose of FAR Part 77 is to identify objects extending vertically through or above these imaginary surfaces, which may pose a hazard to air navigation.

FAR Part 77 surfaces are defined generally below. FAR Part 77 surfaces for Runway 14/32 are listed in Table 3.2-3 and illustrated in Figure 3.2-1.

- **Primary Surface**. This surface is a rectangular surface centered along the runway and at the same elevation as the surface of the runway. The length of this surface extends 200 feet off each paved runway end and the width is dependent upon the characteristics and use of the runway.
- **Approach Surface**. This surface is an inclined trapezoidal plane beginning at the narrow end of the Primary Surface and extending outward and upward. The inner, (starting) edge of the Approach Surface is the same width as the Primary Surface; the approach widens at a uniform rate and the outer edge varies with the runway approach minimums. Since approaches only will occur to the 32 end of unidirectional Runway 14/32, the Approach Surface requirements only apply to the 32 end.
- **Transition Surface.** This surface extends upward and outward from the long sides of the Primary Surface at a slope of 7:1 and meets the Approach Surfaces. Since there is no approach surface for the Runway 14 end, the Transition Surface was assumed to "cut off" at the Runway 14 end, terminating the 7:1 slope.

Table 3.2-3
FAR Part 77 Surfaces for Runway 14/32

Type of Surface and Geometric Parameters	Runway 14 End	Runway 32 End
Primary Surface		
Total width (in feet)	500[1]	500
Distance from centerline on each side (in feet)	250	250
Approach Surface[2]		
Inner width (in feet)	Not Applicable	500
Outer width (in feet)		4,000
Horizontal Length (in feet)		10,000
Slope (horizontal: vertical)		34:1
Transition Surface		
Slope (horizontal: vertical)	Not Applicable	7:1

1 Future use of a Global Positioning System for this runway could require up to a 1,000 foot wide Primary Surface (centered on the runway).
2 Runway 32 end only because approaches will only be permitted to the Runway 32 end of the unidirectional runway.

massport

Figure 3.2-1

Runway 14/32 FAA Design Surfaces

A good way to visualize the shape of each of these surfaces is to imagine an oval soccer stadium, which is closed at both ends, and with the runway running down the middle of the field. The Primary Surface may be envisioned as the flat, grassy surface of the playing field, including and extending out on each side of the runway. The stadium rows behind the goal posts represent the approach surfaces. The stadium rows along the length or sidelines of the field represent the transition surfaces.

It should be noted that the location of the Hyatt Hotel precludes the use of Runway 14 for arrivals, because the hotel penetrates the Part 77 approach surface for a VFR runway.

3.2.2.2 Physical Description of Runway

Proposed unidirectional Runway 14/32 would have a length of 5,000 feet and a width of 100 feet, with 35-foot paved shoulders on either side. At either end of the runway, 1,000-foot long paved runway safety areas (RSAs) would be provided. Since the runway would only be used in one direction, no taxiway to the Runway 32 end is necessary. A small paved turnout area would be provided to allow an aborted departure to be moved off the runway and to reverse direction before returning to the terminal area.

The lighting for Runway 14/32 would include runway edge, end and thresholds lights, and Runway End Identifier Lights (REIL). These lights will be low to the ground and will be placed in accordance with FAA regulations for spacing and intensity. Because Runway 14/32 is slated to be a non-precision runway, an approach lighting system is not necessary. Markings will consist of centerline, edge line, threshold, and runway designator markings. Touchdown zone and aiming point markings would be applied for the Runway 32 end.

3.2.2.3 Runway Layout Options

Three layout options for a 5,000-foot unidirectional Runway 14/32 were developed based upon alternative treatments for the RSA on the Runway 32 end. With the exception of the RSA, each option includes identical design parameters as discussed in the previous section. Each option has been developed in sufficient detail to identify preliminary impacts, and thereby, selection of a preferred layout option. The options are designated A, B and C and are described below.

Option A

Option A, which is illustrated in Figure 3.2-2, meets all FAA runway design criteria and standards. Both runway ends have full 1,000-foot by 500-foot RSAs per the guidelines of FAA's Advisory Circular 150/5300-13 *Airport Design*. A portion of the RSA south of the runway would extend over water.

Option B

Option B, which is illustrated in Figure 3.2-3**,** is shifted approximately 260 feet to the east of Option A. The RSA centerline at the Runway 32 end is placed at the most easterly point of land. To accommodate the full 500-foot width of the RSA of the runway ends, a deck would be constructed or fill would be placed into Boston Harbor (affecting an area of approximately 62,000 square feet). Both runway ends would have full 1,000-foot by 500-foot RSAs, thereby meeting FAA's RSA design guidelines. A portion of the RSA south of the runway would extend over water.

Option C

The alignment of Option C is identical to that of Option B; however, a deck or fill would not be constructed. Instead, a determination of acceptance of the level of safety will be sought from the FAA for the two small, triangular corners of the Runway 32 end RSA and the portion of the RSA south of the runway, which lie over water. The revisions to the runway safety area standard can be adopted if it is determined that it will provide an acceptable level of safety. The Runway 14 end will have a standard 1,000-foot by 500-foot RSA. Option C is illustrated in Figure 3.2-4.

Based on the preliminary engineering conducted in this phase, it is expected that the FAA will agree that it is not feasible and practical (based on cost, engineering and environmental conditions) to develop the areas needed to provide a full RSA. The FAA will determine that the Runway 32 RSA would provide an acceptable level of safety.

Terminal En Route Procedures

Preliminary analysis of the proposed unidirectional Runway 14/32 indicates that the FAA will be able to develop procedures in accordance with Terminal En Route Procedures (TERPs). Appropriate procedures consistent with TERPs standards for approaches and departures can and will be incorporated in the final design process for the runway.

3.2.2.4 Assessment of Technical and Environmental Issues

This section summarizes an assessment of the layout options that was conducted as part of the Airside Project Draft EIS/EIR. This assessment was performed in sufficient detail to discern relative differences among the options and to lead to the selection of a preferred design option, Option C, which was analyzed in detail in the Airside Project Draft EIS/EIR.

Technical issues were assessed by applying the FAA design criteria and standards described above. Environmental issues assessed include impacts to marine habitat in Boston Harbor, and as a general measure of environmental impacts, identification of the local, state and federal wetlands and water resources permits required. All impacts of each alternative are presented in Table 3.2-4.

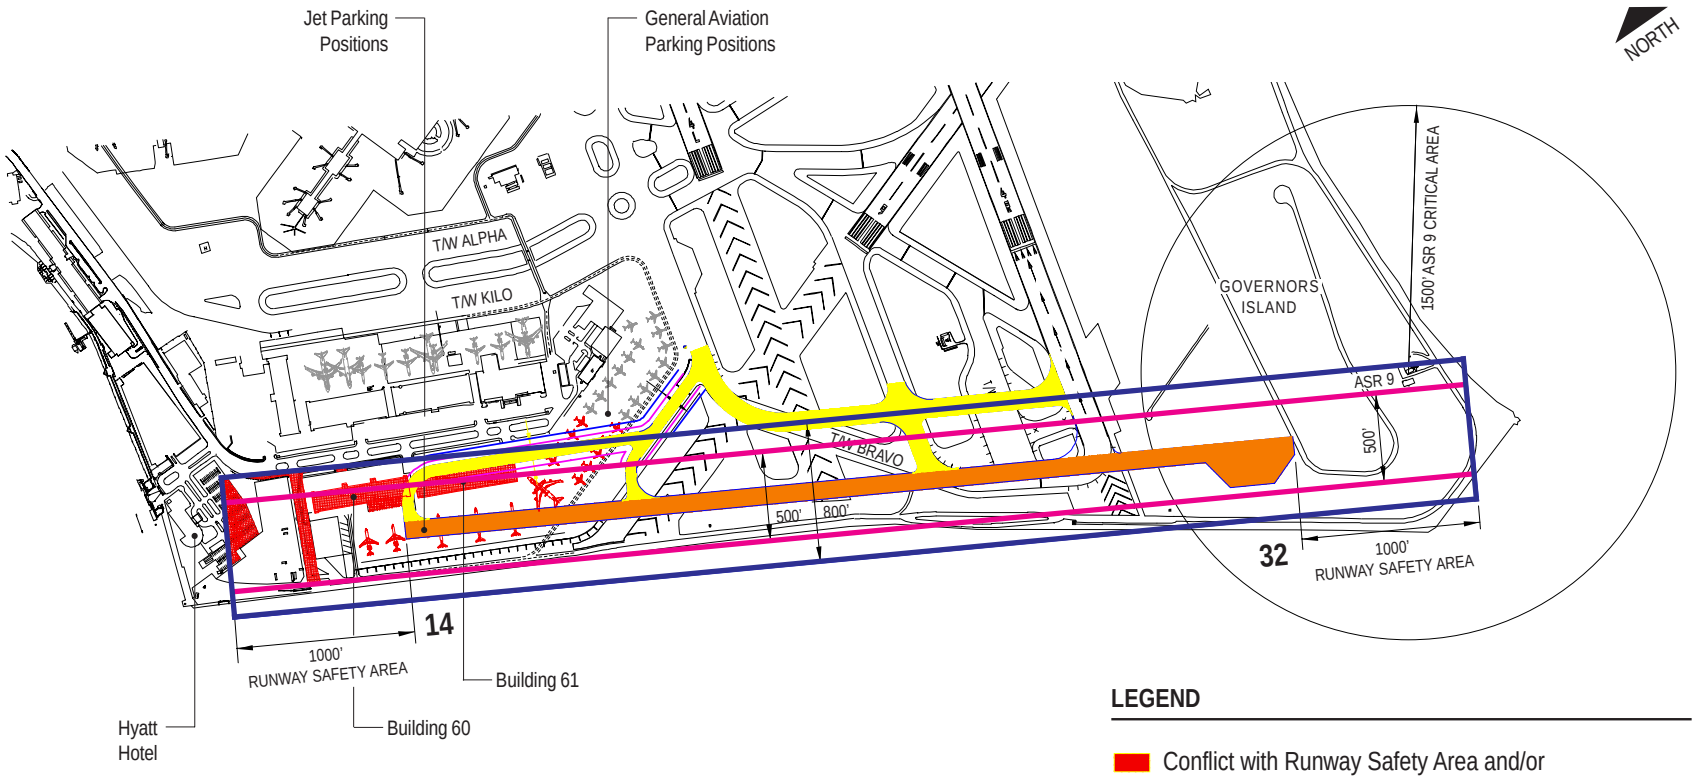

Figure 3.2-2

Table 3.2-4
Summary of Impacts of Runway Layout Options

Impact Type	Impact of Layout Option		
	Layout Option A	Layout Option B	Layout Option C
Building Demolition[1]	Demolish Building 60 which falls within the Runway Safety Area and Runway Object Free Area.	Same as Option A	Same as Option A
Aircraft Parking[1]	Relocate 4 jet and 8 general aviation parking positions elsewhere on the airport.	Same as Option A	Same as Option A
FAA Technical Standards[1]	Runway 14 FAR Part 77 and Taxiway Object Free Area Penetrations[3]	Same as Option A	Same as Option A
FAA Technical Standards	N/A	N/A	Runway 32 Safety Area would not meet standard[4]
Elimination of Vehicular Parking	174 spaces associated with Harborside Hyatt Hotel (71 percent of all parking at Hyatt), with no comparable relocation options.	None	None
Marine Impacts	None	62,000 square feet of deck or fill over Boston Harbor at estimated cost of $8 million	None
Environmental Permits Required	Coastal Zone Consistency Review	Same as Option A	Same as Option A
	Order of Conditions, NPDES Permit for Construction Activities	Same as Option A	Same as Option A
	Air and Water Quality Certification from the Governor (USC 47106 (c(1)(B))	Same as Option A	Same as Option A
		Section 404 Permit, Water Quality Certificate, Chapter 91 License	

1 Impacts common to all three layout options.
2 Building 61 is slated for demolition as part of a separate project.
3 Minimal impact with installation of obstruction hazard lights – all obstructions are located on edge of "unused" Runway 14 end (no arrivals).
4 Two corners totaling 12 percent of the RSA would lie over the water. A request for a determination of an acceptable level of safety will be requested from the FAA.
5 NPDES - National Pollutant Discharge Elimination System Permit

Impacts Common to All Layout Options

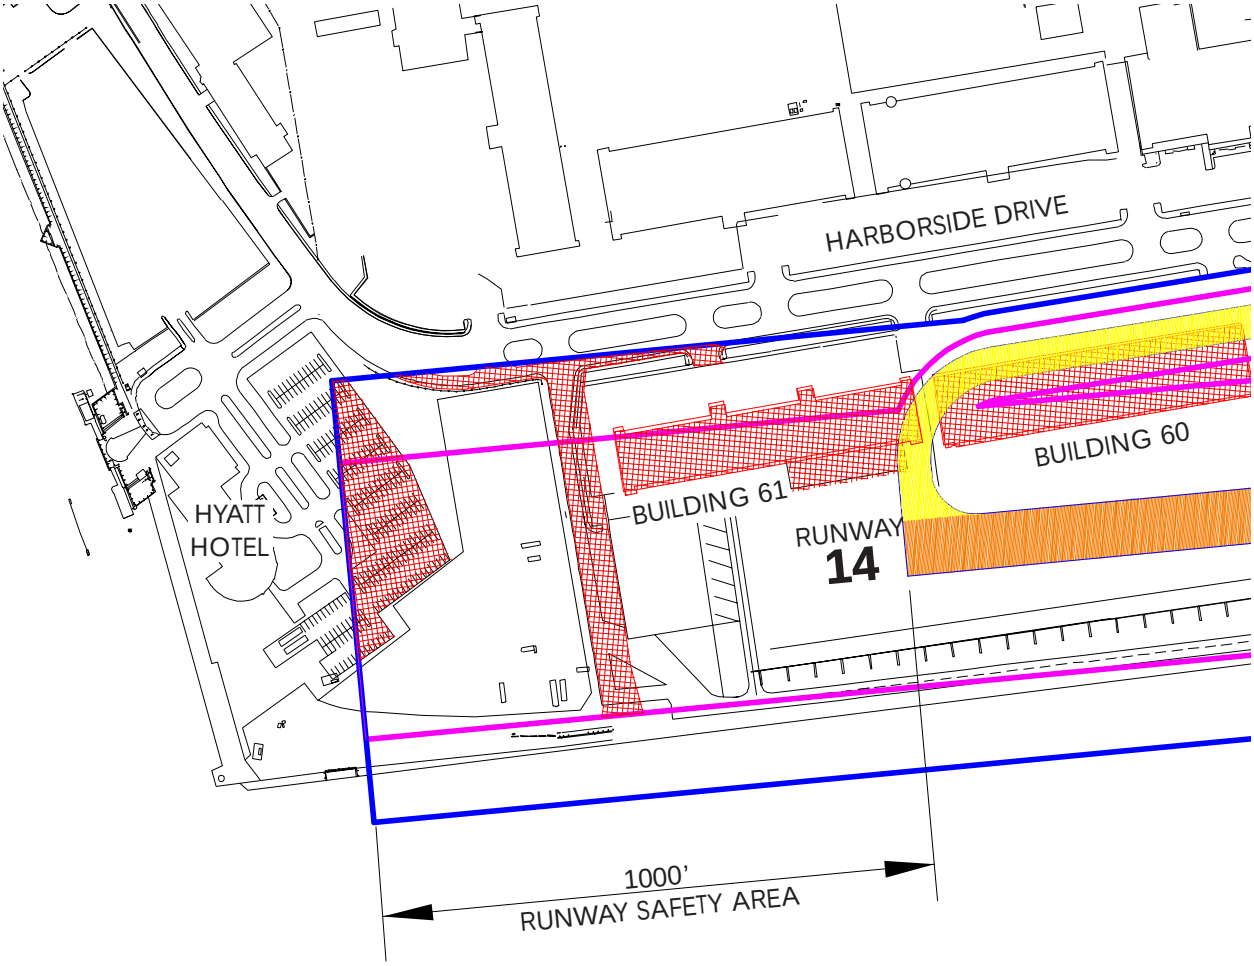
There are several technical and environmental impacts common to all three options. Since these impacts do not serve to discern relative differences between the layout options, they are listed here briefly. Section 3.2.2.4 of the Airside Project Draft EIS/EIR provides a more detailed description of these impacts.

- Two cargo buildings located off of Harborside Drive in the Bird Island Flats area, Buildings 60 and 61, fall within the RSA and ROFA of each layout option, and must be demolished; however, Building 61 is planned to be demolished as part of another project and therefore is not an impact of Runway 14/32. (see Figure 3.2-2)
- Four jet parking positions and eight general aviation daytime positions near Building 60 must be relocated elsewhere on the airport (see Figure 3.2-3).
- Harborside Drive falls within the edge of the FAR Part 77 Primary Surface and a corner of the ROFA at the Runway 14 end. Vehicles traveling on Harborside Drive would intrude on these areas. In addition, the Hyatt Harborside Hotel (Hyatt) and Buildings 56 and 57, located to the northeast of Harborside Drive, penetrate the FAR Part 77 Transition Surface. All of these obstructions are located on the edge of the Runway 14 end that will not be used for arrivals. In accordance with FAA regulations, obstruction hazard lights will be installed on the buildings.
- A portion of the RSA to the south of the runway would extend over the water (approximately 86,000 square feet). The FAA has conducted preliminary analysis of the RSA along the south side of the runway and has concluded that they would be able to make a determination that it provides an acceptable level of safety.
- Permit requirements include an Order of Conditions from the Boston Conservation Commission and a National Pollutant Discharge Elimination System (NPDES) permit for construction activities from the US Environmental Protection Agency (EPA)/MA Department of Environmental Protection (DEP).

Impacts Specific to Individual Layout Options

Option A

Option A places Runway 14/32 furthest to the west of the options under consideration and would eliminate 174 parking spaces associated with the Harborside Hyatt Hotel, at the Runway 14 end. Of the 174 affected spaces, 162 spaces are directly impacted, since parking is not allowed within the RSA and the Runway Object Free Area (ROFA). Twelve additional spaces would be lost as a result of reconfiguring driveways to maintain access to existing spaces. The 174 lost spaces represent 71 percent of the existing 241 spaces at the Harborside Hyatt (see Figure 3.2-5). No comparable relocation options exist. Consequently, acquisition of the affected 174-parking space area by negotiation is highly unlikely and acquisition by eminent domain would likely not be resolved without costly and protracted litigation.



LEGEND

- Conflict with Runway Safety Area and/or Runway Object Free Area
- Runway and Taxiway Object Free Area (OFA)
- Runway and Taxiway Safety Area (SA)

Figure 3.2-5
Runway 14/32 Layout Option A - Potential Impacts to Parking Associated with the Hyatt

7466-FIG-3.2-5.p65

While no modification of FAA standards for the Runway 32 end RSA is required by this option, the impacts on the Hyatt and related costs could potentially be avoided through a modification of RSA and ROFA standards.

Option B

Option B shifts the runway and RSA 260 feet to the southeast (i.e., further away from the Harborside Hyatt) to avoid the Hyatt Hotel's parking lot. As a result, the outer corners of the Runway 32 end RSA are pushed out over the water. Option B includes construction of a deck over the water or fill that covers approximately 62,000 square feet of the harbor, in order to provide the full safety area on the Runway 32 end. Preliminary cost estimates indicate that a deck would cost approximately $8 million (1996 dollars).

The deck or fill may generate direct impacts to marine life and indirect impacts due to the loss or alteration of intertidal habitat. This activity would require the following environmental permits: U.S. Army Corps of Engineers Section 404, Coastal Zone Consistency Review, Water Quality Certificate, Chapter 91 license, NPDES permit, and an Order of Conditions from the Boston Conservation Commission. In addition, since this options requires work in the Harbor, a "Reasonable Assurance letter for Water Quality" from the Governor of the Commonwealth would be required.

Option C

Option C has the identical layout / alignment as Option B, except that no structures would be constructed to accommodate the two small corners of the Runway 32 RSA that lie over the water. Instead, a determination of an acceptable level of safety, would be requested from the FAA. The two corners represent approximately 12 percent of the full RSA area at the Runway 32 end.

In considering a determination, the test is whether an acceptable level of safety can be maintained with the proposed conditions. Three factors are considered:

- An analysis of aircraft accident locations off runway ends based on national statistics;
- The types of aircraft reasonably expected to operate on the runway; and,
- The conditions of use and practical constraints for the runway RSA based on environmental, physical, or cost factors.

Based on an evaluation of these factors, which is discussed in detail in Section 3.2.2.4 of the Airside Project Draft EIS / EIR, the proposed determination for the Runway 32 RSA will not compromise safety because:

- The proposed Runway 32 RSA is a full 1,000 feet long on the centerline.
- The NAVAIDS to be installed would provide added glide path and alignment guidance in Instrument Meteorological Conditions (IMC).

- Available statistical data show that the small over-water corners of the RSA will not significantly affect the safety of operations to Runway 14/32, even for larger group C-III aircraft.[11] Historically, reported undershoots under the conditions for which Runway 14/32 would be used have been on the centerline and within 1,000 feet of the Runway.

The FAA has conducted a preliminary analysis of the RSA on the southeast (Runway 32) end and along the south side of the runway, and has concluded that it would be able to issue a determination that it provides an acceptable level of safety.

3.3 Taxiway Improvements

Four proposed taxiway improvements are described in this section. For each taxiway, the purpose and general effects of the improvement on Logan's airfield operations are summarized. All four of the taxiway improvements would be included in each of the build alternatives: Alternatives 1 and 1A, which include Runway 14/32, and Alternative 2, which does not include Runway 14/32. Each of the taxiway improvements would improve Logan's airfield efficiency, with or without Runway 14/32. Each proposed taxiway has a paved width of 170 feet, which includes a 100-foot wide taxiway and two 35-foot paved shoulders.

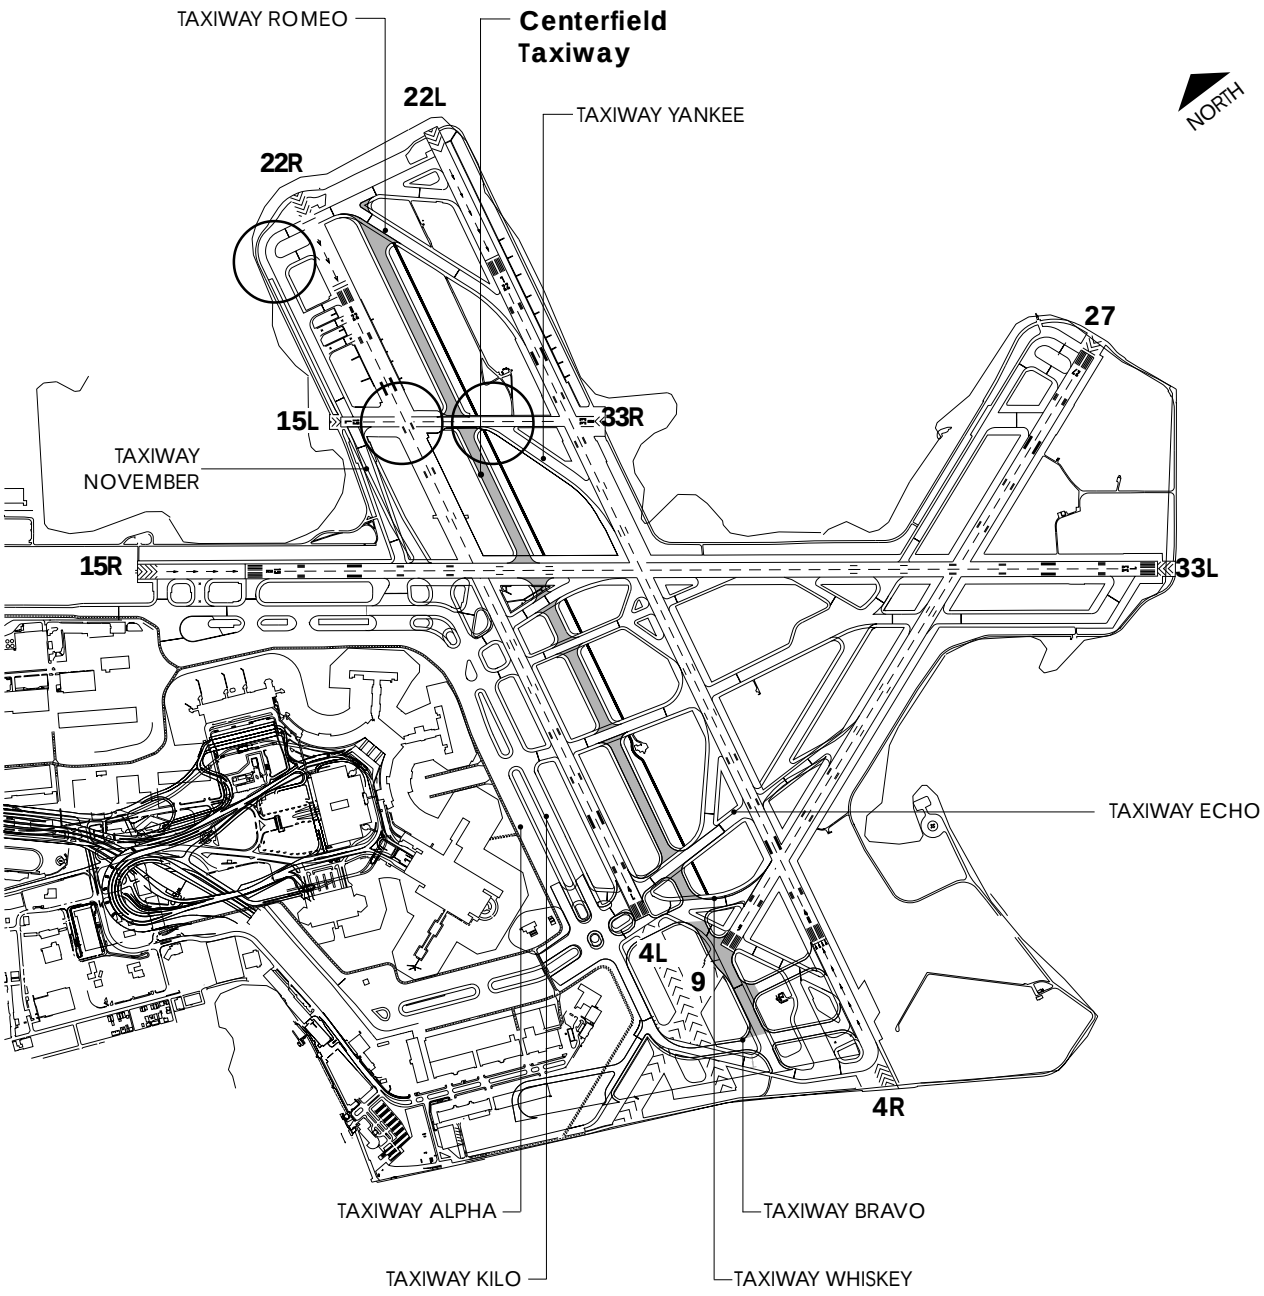
3.3.1 Centerfield Taxiway

A new 9,300-foot Centerfield Taxiway would be located between Runways 4L/22R and 4R/22L, as shown in Figure 3.3-1.[12] The purpose of the Centerfield Taxiway is to provide alternative taxi routings for more efficient movement of aircraft between runways and terminal areas. Improved taxi routes will reduce ground delays for both arriving and departing aircraft. By diminishing delays, particularly north of Runway 15R/33L, the Centerfield Taxiway would reduce both ground noise and air quality impacts associated with ground operations. The Centerfield Taxiway would also alleviate congestion in the vicinity of Terminals B and C, and it would enhance the general safety of airside operations. Specifically, a Centerfield Taxiway would have the following operational benefits:

- **Reduce taxiing delay for Runway 4R arrivals**. Instead of queuing on Runway 33R to cross Runway 4L and then all taxiing single-file down taxiway November, many aircraft could immediately proceed southbound between the runways and then cross Runway 4R at one of several taxiways nearer their gates.

11 DOT/FAA/AOV 90-1 " Location of Commercial Aircraft Accidents/Incidents Relative to Runways," FAA Office of Safety Oversight, July 1990.

12 A Centerfield Taxiway, positioned between Runways 4L/22R and 4R/22L, was initially proposed in 1990 as part of Massport's annual airfield improvements program. An ENF was filed for that program and a Scope for a Draft EIR was issued by the Secretary of the EOEA, pursuant to MEPA. That project (EOEA No. 8108) was later withdrawn by Massport. The layout of the Centerfield Taxiway concept as proposed in this Supplemental Draft EIS/FEIR differs from the 1990 proposal in that the current proposal extends south to Taxiway Bravo to incorporate reconfiguration of the Southwest Corner taxiway system (see Section 3.3.2). The earlier concept terminated at Taxiway Whiskey.



massport

Figure 3.3-1
Centerfield Taxiway

mawald.ld.07466\graphics\figures\StAloneGraphics\Ch3.p65 3\12\2001

- **Reduce taxiing delays for Runway 22L departures**. Currently, aircraft needing the greater departure length of Runway 22L must queue up on Taxiway November with the rest of the departures using Runway 22R. This causes delays for aircraft using both runways during heavy traffic periods. The Centerfield Taxiway would permit the Runway 22L departures to cross Runway 22R near the terminals and proceed directly to the runway, where they would be ready for takeoff as soon as a gap occurs in the Runway 22L arrival stream. Although some comments have argued that this would increase the "stacking" of aircraft in the northern section of the airfield, it would in fact reduce the total delay experienced by both Runway 22R and 22L departures.

- **Decrease taxiing delays for Runway 22L and Runway 27 arrivals**. Similar to the Runway 4R arrivals discussed above, the Centerfield Taxiway would enable many of these arrivals to proceed northbound to a taxiway nearer their gate, and then several could cross Runway 22R simultaneously.

- **Ease congestion near Terminals B and C**. Due to its proximity to these terminals, aircraft using Taxiway Alpha are frequently delayed by aircraft entering or leaving their gates in this area. This congestion would be reduced by using parallel paths on Taxiway Kilo and the Centerfield Taxiway instead of Kilo and Alpha, thereby freeing Taxiway Alpha for pushbacks.

- **Reduce the potential for wing-tip clearance conflicts on Taxiways Alpha and Kilo**. The large wingspan of the newer generation of heavy jets prevent them from passing on the closely spaced taxiways Alpha and Kilo. Using Taxiway Kilo and the Centerfield Taxiway would avoid such problems.

The Centerfield Taxiway would not change the total number of aircraft operations which cross an active runway, but it would substantially reduce the delays experienced by these aircraft, particularly for arrivals. Instead of forming a single queue to cross Runway 4L/22R single-file, they could be dispersed to multiple crossing points where several could cross the active runway at the same time.

In general, a Centerfield Taxiway would decrease taxiing distances and taxiing times for most airfield operating configurations, and would also move points of congestion away from residential areas. The Taxiway would reduce the potential for runway incursions, would enhance safety by decreasing congestion on the taxiway system, and would provide controllers with greater flexibility to improve the efficiency of airport ground operations.

3.3.2 Southwest Corner Taxiway System Reconfiguration

Changes to the taxi layout in the Southwest Corner of the airport near the ends of Runways 4L, 4R and 9 will simplify a confusing jumble of taxiways, reduce the opportunities for runway incursions, and expedite ground movements in this area. Reconfiguring the existing taxiways will improve the access of departures to Runways 4L, 4R and 9, and will provide a more logical and streamlined flow for inbound and outbound aircraft when Runways 27 and 33L are active (see Figure 3.3-2).

The Southwest Corner reconfiguration would enhance safety and operating efficiency by simplifying runway crossings and access in a section of the airfield that may be confusing to some pilots, particularly at night or during reduced visibility. It would also allow Runway 14/32 to be used as a taxiway in some runway configurations to improve flexibility and ground movement efficiency.

3.3.3 Taxiway Delta Extension

Taxiway Delta would be extended 2,000 feet between Taxiway Charlie and Runway 4R/22L (see Figure 3.3-3). The completion of Delta would provide an alternate path for departures on Runways 27 and 33L, thereby reducing congestion on Taxiway Charlie that now is the sole access to these runways. This would improve efficiency by separating jets taxiing to Runways 27 and 33L from non-jets using Taxiways Charlie and Golf for Runway 33L intersection departures.

3.3.4 Taxiway November Realignment

Approximately 2,200 feet of Taxiway November would be realigned between Runway 15L/33R and Runway 15R/33L to simplify its connection to Taxiways Kilo and Alpha which provide the main flow around the terminal areas (see Figure 3.3-4). In addition, this improvement would eliminate the confusing simultaneous intersection of Taxiway Tango with both Runways 33L and 22R. These changes would not only improve efficiency but also enhance safety by reducing the potential for runway incursions, especially at night and during reduced visibility.

3.4 Reduced Approach Minimums for Runways 15R, 22L, 27, and 33L

This improvement concept proposes to reduce the current approach minimums on four existing runways at Logan to FAA values which are provided at most other airports in the nation. The "approach minimum" is the lowest point along the existing glide slope during the approach (landing) at which the pilot must make a decision whether to land or to execute a missed approach procedure, when the visibility is low. The approach minimum for each runway is established by the FAA based upon the type of navigation equipment available, the existence of obstacles in the approach area, and performance of the aircraft. The approach minimums are established and published for each runway by the FAA. Lowering the minimums would not change the altitudes at which aircraft operate, but just the distance from the runway where the missed-approach decision is made.

Five of Logan's runway ends are equipped with precision electronic navigation systems (Instrument Landing Systems - ILS) and approach lighting systems, which enable aircraft to land under low visibility weather conditions. At the present time, only Runway 4R, which is equipped with a Category III ILS, is approved for the lowest approach minimum established by FAA. This adds to greater use of and dependence on Runway 4R under poor weather conditions. This section summarizes proposed changes to the approach minimums at the other four runways, which are also described in Section 3.4 of the Airside Project Draft EIS / EIR.

Although Runways 15R, 22L, 27 and 33L are each equipped with a precision Category I ILS, those on Runways 22L and 27 currently have approach minimums that are artificially constrained and are significantly higher than the capabilities of the existing electronic equipment permit. When the ILSs were installed on Runways 22L and 27 several years ago, the FAA agreed to retain the existing non-precision approach minimums until the appropriate new values could be addressed in an EIS. Reduction of the approach minimums on Runways 22L and 27 to ILS Category I values that are consistent with current FAA standards is included in all improvement alternatives. The existing and proposed ILS minimums are shown in Table 3.4-1.

The existing ILS approaches to Runways 15R and 33L are also proposed to be improved. The planned action includes upgrading these approaches to Category III ILSs, which would permit landings on these runways down to the same approach minimums as on Runway 4R. The availability of additional precision navigation equipment on these two runways would provide improved operational flexibility to air traffic controllers and enhance safety during adverse weather conditions.

Lowered minimums on these four runways would extend the range of weather conditions under which they could be used and would thereby reduce reliance on Runway 4R during low visibility. This would provide improved operational flexibility and thereby reduce delays as well as increase the opportunity to achieve PRAS goals, particularly the short-term dwell and persistence.

Table 3.4-1
Existing and Proposed ILS Minimums* for Runways 15R, 22L, 27, and 33L

Runway		Cloud Ceiling		Visibility	Distance of Decision Height Point from Touchdown		Runway Availability
		Feet Above Ground Level	Mean Sea Level Elevation (feet)	Statute Miles)	Feet	Nautical Miles	Annual Hours, 1980 – 1990 Weather
15R	Existing	250	268	3/4	4,800	0.79	5,356
	Proposed	0	18	1/8	0	0.00	5,495
22L	Existing	403	420	1-1/4	7,700	1.27	6,835
	Proposed	200	217	1/2	3,800	0.63	6,929
27	Existing	443	460	1-1/2	8,500	1.39	6,972
	Proposed	200	217	1/2	3,800	0.63	7,055
33L	Existing	200	217	1/2	3,800	0.63	7,173
	Proposed	0	17	1/8	0	0.00	7,249

* Lowest minimums possible. Some may be gradually achieved.

Table 3.4-1 shows the change in availability of each runway due to reduced minimums. An analysis of the 37.5M Low Fleet demonstrated that reduced minimums alone provide an annual delay reduction of approximately 6,000 hours as a result of greater runway availability under poor weather conditions. Appendix D of the Airside Project Draft EIS/EIR provides additional discussion of reduced minimums and their associated delay benefits.

3.5 Peak Period Pricing

Peak Period Pricing is a demand management tool that is intended to reduce delays caused by situations where flight demand exceeds airfield capacity over a sustained period. Peak Period Pricing works by raising the price of using the airfield during designated peak hours. As a result, some existing aircraft operations would be discontinued if the cost of using Logan during the peak would exceed the value of the economic return to the carrier.

Peak Period Pricing was chosen from alternative demand management strategies because it has been effective in other industries and because it is excluded from review under Part 161 of the Federal Aviation Regulations, which sets standards for airports that wish to restrict access for Stage 3 aircraft. Other demand management tools, such as slots or caps, are discouraged under current federal guidelines and would require extensive analysis under Part 161. The current environment where Congress has moved to eliminate slots at High Density Airports suggests that imposing slot controls would not be approved.

Current flight activity levels at Logan do not exceed available airfield capacity during VFR conditions. Airline overscheduling has not been a significant cause of delays at Logan since 1993. Nonetheless, the effect of Peak Period Pricing on delay was evaluated for its potential to reduce delay under future conditions should airline overscheduling re-emerge.

Chapter 3 of the Airside Project Draft EIS/EIR provided descriptions of previous Logan programs, the procedural requirements for implementing Peak Period Pricing, and the screening analysis used to determine the Peak Period fee that was tested across all future fleet scenarios. This section discusses alternative demand management practices, their use at other airports, and previous initiatives at Logan.

3.5.1 Demand Management Policies at Other Airports

The FAA requested that the Supplemental Draft EIS/Final EIR identify demand management strategies that are in use or have been proposed by other airports. Presently there are few examples of demand management policies employed at other United States airports. The most notable example of demand management in the United States was the imposition of slot restrictions at several of the nation's most congested airports in 1969.

Demand management techniques can be generally classified as either regulatory or economic. The former establishes a limit on the number of flights that can be accepted at an airport, i.e., slots, while the latter charges airfield users a higher fee during the busiest periods in order to reduce demand. Sometimes a combination of the two is employed.

3.5.1.1 Regulatory Approaches

These are the most common techniques used by airports worldwide to control airport demand, but have seen relatively limited application in the United States. In the United States, under FAA guidelines, a regulatory approach would be construed as an airport access restriction, and would therefore require an airport to conduct a Part 161 Study.

Slots

Most of the world's major international airports outside the United States use slot controls to limit traffic to an acceptable level. The slots are negotiated by a Slot Committee which meets periodically to review and revise the allocation of landing slots at the major airports. Each participating airport is represented on the committee, often by the home country's flag carrier. The number of slots for a given airport is set by the airport management or local government authority, and a prescribed number are usually reserved for the local carriers.

In the United States, slots are used at only four High Density airports (Chicago O'Hare, Washington Reagan National, New York JFK and New York LaGuardia). The number of slots per hour is set by the FAA for air carriers, commuter operators and general aviation. At LaGuardia, for example, access was restricted to 68 hourly operations between 6:00 A.M. and midnight. Of these, 48 were allocated to air carriers, 14 to commuter carriers,

and six to charter operators, general aviation, military, or airline extra-section operations. Until the passage of slot reforms in April 2000, the number of slots has changed only slightly at these airports since the program commenced in 1969.

Passenger Caps

This method is used occasionally in the United States, generally at smaller airports. It can restrict the annual volume, or set a short-term (e.g. half-hourly) limit on passengers carried. Examples include Orange County in California and Westchester County in New York.

Perimeter Rules

This technique controls demand by placing a limit on the originating or destination airports that can be served from the constrained airport. Washington Reagan National and New York LaGuardia are the primary examples of perimeter rules in the United States. These perimeter rules pre-dated Part 161 requirements.

Gate Use Standards

This method attempts to maximize airfield efficiency by placing a limit on the number of daily seats that a carrier operates through each gate. It is implemented via the airport-airline lease agreement, and forces the carrier to use the gate for its most valued flights and usually larger aircraft. Chicago Midway is a successful example of this approach in operation. Seattle-Tacoma Airport considered this program in 1995, but eventually dropped it due to complications with existing long-term lease agreements.

Aircraft Size Limits

This approach is similar to the gate use standards, but explicitly limits the minimum seat-size of aircraft using the airfield to increase efficiency. It was recently proposed at San Francisco to reduce weather-related delays for flights to / from Western United States cities, but a formal policy was never implemented.

3.5.1.2 Economic Approaches

These methods apply higher fees for flights operating during the peak periods to use the law of supply and demand for controlling activity. The concept often applies differential pricing for different types of users, and usually changes the fee structure by time of day. Several examples are provided below.

London Heathrow

Heathrow Airport has implemented a flat fee per operation (no traditional weight-based landing fee) during peak hour operations for several years. The fee is higher during the hours from 7:00 to 10:59 A.M. and 5:00 to 7:59 P.M. during the summer season. During the off-peak hours, two weight-based aircraft categories are used to calculate landing fees.

New York Minimum Landing Fee / GA Surcharge

In August 1968, the Port Authority of New York and New Jersey (PANYNJ) instituted a minimum landing fee on general aviation during peak periods at the three New York airports. The minimum fee for GA operators was progressively increased and eventually changed to a $100 surcharge (in addition to the traditional weight-based fee). The same minimum fee was subsequently imposed on commuter operators.

Boston Logan Minimum Daily Landing Fee

In 1982, Massport implemented a minimum daily landing fee of $50, applied against the conventional weight-based fee from 8:00 A.M. to 8:00 P.M.. The effect of the minimum was to discourage individual GA flights without penalizing multiple daily flights by small commuter / air taxi operators. Resistance to this program was strong, however, and in less than a year Massport rescinded it.

Boston Logan PACE Program

In July 1988, Massport implemented the Program for Airfield Capacity Efficiency (PACE). PACE represented a modification to Logan's landing fee structure that redistributed costs between users, while maintaining revenue neutrality (i.e., maintaining total airfield revenues at a level that does not exceed total airfield costs). The landing fee formula was changed to include a $91 fixed cost per landing plus $0.45 per 1,000 lbs. As a result of PACE, the cost of using Logan increased substantially for smaller aircraft, and declined somewhat for larger aircraft.

PACE was challenged by operators of small aircraft in US District Court and in an administrative proceeding before the US Department of Transportation (DOT). Summary Judgement upholding PACE was issued by the US District Court. However, the PACE fee structure was found to discriminate against smaller aircraft users by the DOT and, therefore, to be in violation of federal aviation statutes. The US Circuit Court of Appeals upheld the DOT. As a result, PACE was discontinued after only six months of use.

In terms of the instructiveness of PACE to a Peak Period Pricing program, it is important to understand that PACE did not relate to the peak hour at all. Rather, the increased fee applied across the entire day. While many are under the misconception that PACE was effective because of a subsequent decline in Logan regional carrier and general aviation operations, this decline was experienced at other airports in the region and was more related to market factors than PACE. The restructuring of the regional carrier industry at Boston and in New England continued well after PACE was rescinded.

1993 Boston Logan Peak Period Pricing Concept

During 1992-1993, high and increasing levels of delay caused Massport to revise the PACE proposal to reflect the DOT decision. In the modified approach, peak hour fees applied only to the most congested period of the day, and the method of airfield cost allocation was carefully calculated using the utility industry as a model. The resulting peak hour fee proposal had three components: (1) an operations charge for all aircraft

irrespective of weight, (2) a weight based charge, and (3) a peak hour fee between 2:00 PM and 8:00 PM (for both landings and takeoffs). The proposal was designed to be revenue neutral, but the effect on individual users differed. Smaller aircraft would pay more than under the traditional method, and larger aircraft would pay less. The peak hour pricing proposal was taken through the analytical phase and an informal public process with a wide range of interest groups, as well as briefings for the FAA and the DOT Office of the Secretary. In 1993, Massport determined that it was appropriate to reexamine the Logan delay problem from a more detailed perspective, particularly in light of fleet mix changes. The Logan Airside Improvements Feasibility Study was initiated which examined the nature of the delay problem and a broader range of potential delay reduction mechanisms. Peak Hour Pricing was one of the options studied.

Sydney Australia Peak Hour Pricing

In 1989, the Federal Airports Corporation in Australia implemented one of the few true demand management policies at Sydney Airport. The components of this pricing mechanism meet the economic and practical standards for peak hour pricing theory: access to the airport was not controlled by slots or any other regulatory mechanism; the charge was related to the airport's peak congestion period; and the charges applied to both arrivals and departures. The program was initially applied only to general aviation, but extended to all flights in 1991. A flat A$250 fee was charged for each landing or takeoff during peak periods in both morning and evening; during shoulder periods on either side of the peaks, the fee was A$200 per landing and A$100 per takeoff. The Sydney pricing resulted in a 28 percent reduction in peak period flights (all by non-jets), while actually increasing the passenger seat capacity.

Seattle Congestion Management Study

As part of the decision process on a new runway for Sea-Tac airport in 1995, a study of various Peak Period Pricing structures concluded that fees as high as $200 would remove at most seven percent of the peak hour operations.

3.5.1.3 Federal Slot Reforms

In the interests of promoting airline competition and service to underserved communities, the federal government enacted slot reforms through passage of the Federal Aviation Investment Act for the Twenty-First Century ("AIR-21") in April 2000. AIR-21 provides for the phased elimination of slots at the New York airports and Chicago O'Hare. Slot-restrictions at LaGuardia and J.F. Kennedy International will be lifted after January 1, 2007 and slot-restrictions at Chicago O'Hare will be terminated after July 1, 2002. At Washington Reagan National Airport, AIR-21 created 24 new slots.

AIR-21 also created interim slot exemptions for the LaGuardia, J.F. Kennedy International, and Chicago O'Hare Airports. The interim slot rules effectively lifted slot restrictions for carriers wanting to serve small or non-hub communities with small aircraft (under 71 seats) and for new entrant or limited incumbent carriers (carriers with 20 or fewer slots). Although the interim exemptions applied to three of the High Density

airports, the overwhelming majority of airline exemption requests were for LaGuardia. Carriers filed exemption requests for more than 600 additional daily flights at LaGuardia, which would have increased daily scheduled operations by more than 50 percent. Carriers proposed to operate two-thirds of the additional flights with regional jet aircraft and one-third with turboprop aircraft.

By November 2000, airlines were operating more than 200 of the proposed AIR-21 services at LaGuardia, representing a 26 percent increase in scheduled operations over the prior year. The substantial increases in aircraft activity resulted in unprecedented levels of delay at LaGuardia. In September 2000, the FAA OPSNET database showed that LaGuardia experienced more than 9,000 flight delays compared to 3,100 delayed flights a year earlier. The FAA estimates that 25 percent of flight delays in the United States in September 2000 occurred at LaGuardia, compared to approximately 12 percent before AIR-21.

In response to the substantial increases in activity and delays, the Port Authority of New York and New Jersey ("PANYNJ"), which operates LaGuardia, sought voluntary measures from the airlines to minimize airport congestion. In August 2000, the PANYNJ requested that air carriers schedule AIR-21 eligible service outside of the airport's most congested operating hours. The airlines did not respond the PANYNJ's request. Subsequently, the PANYNJ announced a moratorium on new services until a demand management measure could be adopted.

The FAA did not sanction the moratorium and began immediate discussions with the PANYNJ to devise a short-term demand management strategy for the airport. The FAA and the PANYNJ agreed to allocate a limited number of AIR-21 slot exemptions to airlines through a slot-lottery. The allocation of AIR-21 services is an interim measure intended to mitigate the air service disruptions and delays brought on by the AIR-21 slot exemptions. The lottery was conducted in January 2001, and it increased the total number of hourly operations at LaGuardia, which has just two runways, from 68 to 81. As a result, the number of AIR-21 slot exemptions was limited to 150 daily operations. In its decision to allocate flights authorized by AIR-21, the FAA made clear that the lottery was a Federal action and that the PANYNJ could not have acted on its own to limit airport operations.

The FAA is currently in the process of developing a long-term demand management policy that will become effective at LaGuardia in September 2001. Through this process the FAA intends to articulate demand management measures that would be available to all airport operators. It is expected that any demand management policy promulgated by the FAA will be shaped by two recent forces in the aviation industry, the AIR-21 slot reforms and the widespread introduction of regional jet aircraft. The pending FAA decision is expected to result in updated federal guidance for other airports, such as Logan, on the appropriate structure for demand management programs, including Peak Period Pricing.

3.6 Alternative Packages

For analytic purposes, the various airside improvement concepts identified previously were grouped into different packages of alternatives. The alternatives have been structured to provide a clear basis for assessing the operational benefits and environmental impacts of the proposed improvements as compared to each other and the No Action Alternative.

The following sections describe the range of alternatives considered in the Airside Project Draft EIS/EIR and this Supplemental DEIS/FEIR.

3.6.1 Alternative 1 – All Actions

Alternative 1 would involve implementation of all recommended concepts (see Figure 3.1-1). This would include construction of unidirectional Runway 14/32, construction of the Centerfield Taxiway, realignment of Taxiway November, extension of Taxiway Delta, and reconfiguration of the Southwest Corner taxiway layout. In addition, reduced minimums for Runways 22L, 27 and 15R would be implemented and a Category III ILS would be operational for Runway 33L. A Peak Period Pricing surcharge would also be implemented.

In addition to the full analysis of this alternative, several individual case studies for Runway 14/32 were conducted to examine the runway's effectiveness under specific operating and weather conditions. Descriptions and results of these specialized case studies are presented in Appendix H and I of the Airside Project Draft EIS/EIR.

3.6.2 Alternative 1A - All Actions Except Peak Period Pricing

Alternative 1A is a subset of Alternative 1, and includes all improvements except Peak Period Pricing (see Figure 3.1-1). Massport added this alternative to the analysis in response to public comment on the alternatives presented in the Airside Project ENF. Since the initial on-airfield alternatives included Peak Period Pricing in all but the No Action scenario, there was no opportunity to gauge the specific impact of a Peak Period Pricing scenario independent of the runway.

In response to these comments, Alternative 1A was developed by eliminating Peak Period Pricing from Alternative 1. In this manner, by comparing the operational, environmental, and socioeconomic impacts of Alternative 1 with those of Alternative 1A, an understanding of the incremental benefits of Peak Period Pricing is possible.

During the public scoping period and through the Airside Review Committee and SDEIS Panel processes, certain commenters suggested that there was considerable potential for significant adverse economic impacts associated with Peak Period Pricing. To more clearly evaluate and identify the individual effects of a Peak Period Pricing program, specialized case studies which focus on regional carriers and affected markets were also

conducted. Details and findings of these case studies are presented in Appendices E and F of the Airside Project Draft EIS/EIR.

3.6.3 Alternative 2 - All Actions Except Runway 14/32

A second "Build" Alternative was developed to facilitate a clear understanding of how the airfield might operate if all the improvement concepts were implemented except a unidirectional Runway 14/32 (see Figure 3.1-2). Accordingly, Alternative 2 combines all recommended actions other than the runway. All proposed taxiway improvements are included. Comparison of Alternatives 1 and 2 provides insight into the incremental benefit of the proposed unidirectional Runway 14/32 in reducing congestion and delay and the associated environmental impacts.

3.6.4 Alternative 3 - No Build

Alternative 3 is considered to be the No Build alternative in that it consists only of the operational and administrative improvement concepts: i.e., reduced minimums for Runways 22L, 27, 15R, and 33L (includes CAT III ILS), and Peak Period Pricing. Implementation of this alternative would not involve construction of any physical improvements. Comparison of Alternative 3 with Alternative 2 provides insight into the operational and environmental impacts of the taxiway modifications.

3.6.5 Alternative 4 - No Action

The No Action Alternative (Alternative 4) evaluates the impacts of not implementing any Airside Project improvements. It is assumed, however, that routine maintenance and minor annual improvements would be ongoing. Alternative 4 serves as the baseline for evaluating the effectiveness of all alternatives, and provides additional context for assessing the Preferred Alternative.

4 Delay Analysis

Key Points

Logan suffers from a serious aircraft delay problem and is consistently ranked among the most delayed airports in the country. In 2000, Logan was the 6th most delayed airport in the United States in terms of total delays. Logan fared even worse in arrival delays, ranking as the 2nd worst airport in the nation. This is Logan's lowest ranking in the last decade. If no improvements are made, delays will become significantly worse, especially those that the Airside Improvements Planning Project (Airside Project) improvements can alleviate, i.e., those occurring under Visual Flight Rule (VFR) conditions when wind levels (particularly from the northwest) reduce existing runway capacity. If no action is taken to address this situation, total annual delays (runway and taxiway) will increase from an estimated 142,000 hours to as much as 363,000 hours under the 37.5 million passenger High Fleet scenario. The average delay would increase from 17 to 36 minutes per flight.

This chapter reviews the activity forecasts, the delay modeling methodology and the results of the airfield delay analysis with the Preferred Alternative (Alt 1A). While the Airside Project Draft Environmental Impact Statement/Environmental Impact Report (Draft EIS/EIR) provided a discussion of all Alternatives and all fleets, this Supplemental Draft EIS/Final EIR focuses the discussion on the results of the Preferred Alternative compared to the No Action Alternative for the 29 million passenger Low Fleet (29M Low Fleet) and the 37.5 million passenger High Fleet (37.5M High Fleet). These fleets reflect the range of likely future passenger and activity levels. The remaining fleets and Alternatives are described in Appendix C.

In response to the FAA directive resulting from the SDEIS Panel process, this chapter presents a third fleet. This fleet assumes that the 37.5 million passengers will use more regional jets (RJs) and fewer non-jet aircraft than previously forecast, and is called the 37.5M High RJ Fleet. This scenario examines the delay reduction utility of all of the proposed improvements including unidirectional Runway 14/32 and Peak Period Pricing.

The principal findings of this section are as follows:

- Based on the modeling of current conditions, Logan incurs an estimated 120,000 annual hours of runway delay. With the availability of unidirectional Runway 14/32 and the other recommended improvements comprising the Airside Project Preferred Alternative, delays could have been reduced by 32 percent, with a 69 percent reduction in Visual Flight Rules (VFR) delays. Delays during northwest wind conditions would have been reduced by nearly 90 percent.

- The lack of a third available runway in the east-west operating direction causes an unbalanced geographic distribution of jet operations at Logan Airport. Approximately three-quarters of Logan's current jet flights overfly communities impacted by the north/south runway configurations. Under the 37.5M High Fleet scenario, Logan's reliance on north/south runways will increase to over 90 percent. The proposed Runway 14/32 will allow for a more balanced distribution of operations, reducing reliance on the north/south runway configurations to 41 percent.

- The proposed Runway 14/32 will also permit a substantial increase in use of the preferred arrival and departure routes over the water. Under the 29M Low Fleet scenario, approximately 52,000 jet operations, or 17 percent of total jet operations, would shift from flight paths over communities to flight paths over the water. Under the 37.5M High scenario, 89,000 jet operations would shift to flight paths over the water.

- Taxiway improvements will reduce ground delays by 47 percent with the 29M Low Fleet and 26 percent with the 37.5M High Fleet (Alternative 2 vs. Alternative 3) by eliminating constraints and inefficiencies in the taxiway system. The proposed runway also makes a positive contribution to reducing Logan's taxiway delays. With the Preferred Alternative, including the runway, taxiway delays are reduced by 65 to 70 percent (Preferred Alternative vs. No Action).

- A reduction in approach minimums for Runways 15R, 22L, 27 and 33L provides modest delay reduction but significantly enhances safety by increasing runway availability in Instrument Flight Rules (IFR) weather conditions. Reducing minimums does not change the flight path of arriving flights, but moves the decision point for missed approaches towards the airport and, in most cases, within the airport boundary. This will allow the principal noise impacts from go-around operations to occur over the airport, rather than closer to residential areas.

- Peak Period Pricing is designed to reduce delays that occur when airlines schedule flights beyond the airfield's capacity. Overscheduling has not been a significant factor in delays at Logan since 1993, but could reoccur in the future. However, Massport intends to put in place a process that will allow for a timely response to airline overscheduling. Massport has designed an airline schedule monitoring system, and is committed to implementing Peak Period Pricing if airline overscheduling should emerge in the future as a source of delays.

- Peak Period Pricing produces only limited delay reduction benefits under near- and long-term Low Fleet scenarios. For example, under the 29M Low Fleet scenario, Peak Period Pricing would incrementally reduce runway delays by 2 percent or less, while imposing over $6 million in additional costs on Logan's regional carriers and potentially impacting access to Logan from small communities. However, under the long-term High Fleet scenario which is characterized by airline overscheduling, Peak Period Pricing provides meaningful delay reduction benefits.

- Incorporating an exemption program for small communities would reduce the expected degree of service disruption resulting from Peak Period Pricing. With a limited number of exemptions, the delay reduction benefits of Peak Period Pricing could generally be maintained under the High Fleet scenario where airline overscheduling is a significant cause of Logan delays.

- An additional future fleet scenario was developed and evaluated for this Supplemental DEIS/FEIR, the 37.5M High RJ Fleet. This fleet is characterized by a substantial volume of regional jet aircraft and a reduced level of non-jet operations.

- Independent FAA analysis examined the probable utilization of the 5,000-foot runway by regional jets and determined that the runway length would be acceptable for most of the regional jet types projected to operate at Logan.

- Based on the runway utilization assumptions provided by the FAA consultant, approximately 70 percent of the regional jet aircraft in the 37.5M High RJ fleet will be able to land on Runway 32. Operational analysis of the 37.5M High RJ Fleet found that the Preferred Alternative would reduce annual delays by 109,000 hours, or 29 percent when compared to the No Action Alternative.

- Placing a northwest wind restriction on Runway 14/32 would limit the increase in jet departures on Runway 27 that results from the availability of a third three-runway configuration at Logan. However, this restriction would sacrifice a portion of the delay reduction benefits provided by Runway 14/32, and would also limit the level of the relief provided to communities impacted by the north/south runway configurations which are already the most heavily utilized at Logan.

- The illustrative Peak Period Pricing program with a $150 surcharge was ineffective at reducing delays under the 37.5M High RJ Fleet scenario. A higher peak fee would be required to provide meaningful delay reduction under this scenario, principally due to the higher revenue and profitability of regional jet services as compared with non-jets. An effective Peak Period Pricing program that would eliminate overscheduling in the 37.5M High RJ Fleet was projected to reduce runway delays by approximately 68,000 annual hours or 18 percent (Alternative 2/3).

- Since the original 1983 version of the Preferential Runway Advisory System (PRAS), two major enhancements have been installed in the FAA control tower. The PRAS enhancements have led to significant improvements in PRAS conformance, despite increasing levels of flight activity at Logan.

- Massport has designed protocols to assess achievement of PRAS goals and is committing to: (1) publish results on a more regular basis, (2) broaden its distribution list, and (3) expand the set of reported data to provide a more complete representation of PRAS conformance.

4.1 Overview

Logan suffers from a serious aircraft delay problem and is consistently ranked among the most delayed airports in the country. The airfield's VFR capacity of approximately 120 operations per hour is sufficient to accommodate current levels of aircraft demand. However, delays accrue when weather conditions, particularly strong northwest winds, lower airfield capacity to levels well below normal operating conditions. If effective measures for dealing with delays are not implemented, the disproportionate level of delays at Logan will continue to worsen.

While Massport and the FAA cannot entirely eliminate delays at Logan, the proposed runway will improve Logan's reliability and reduce delays by preventing the decline in airfield capacity that now occurs in northwest winds. The proposed improvements will also enhance the safety and efficiency of Logan's runway and taxiway systems and provide increased operating flexibility, particularly during periods of low visibility.

This chapter describes the delay and operational analyses that were used to evaluate the proposed improvements and analyze the impacts of the Preferred Alternative. The evaluation considered a range of forecast passenger and aircraft activity levels at Logan to provide a full understanding of the potential benefits and impacts of the recommended improvements.

In the Airside Project Draft EIS/EIR, historic Logan activity from 1993 was used to provide historical context to the assessment of aircraft delays and environmental impacts. For this Supplemental DEIS/FEIR, these 1993 conditions were supplemented and updated with an analysis of Logan operating conditions during 1998. By including this analysis, the Supplemental DEIS/FEIR provides an assessment of more recent delays at Logan and quantifies the delay reduction benefits that would occur with the recommended Preferred Alternative. The 1993 and 1998 analysis conditions are described in Section 4.2.

Since the Airside Project Draft EIS/EIR forecasts were originally developed in 1995, Section 4.2 also analyzes recent changes in passenger demand, airline fleets, and airline scheduling. Based on these trends, an additional fleet forecast, the 37.5M High RJ scenario, was developed to ensure that the airside analysis considered an appropriate range of future conditions.

Some comments received on the Airside Project Draft EIS/EIR expressed a concern that the Preferred Alternative could stimulate an increase in passenger traffic and/or aircraft operations. Therefore, this section also includes a discussion of induced demand, explaining that implementation of the Preferred Alternative will not cause growth in Logan passengers or operations or impact the timing of expected growth.

While delay reduction is a principal objective of the recommended Airside Project improvements, proposed Runway 14/32 enables air traffic controllers to better achieve the goals of the Preferential Runway Advisory System (PRAS) or any other preferential runway system where a more equitable distribution of noise is the objective. Section 4.3 of this chapter provides a thorough discussion of PRAS, including its history at Logan, recent enhancements to the PRAS system, and the improvement in historic PRAS conformance facilitated by those enhancements.

In response to the Executive Office of Environmental Affairs (EOEA) Secretary Certificate on the Airside Project Draft EIS/EIR (May 7, 1999), this section also includes discussions of improved monitoring and public reporting of PRAS conformance and of the potential for extending the current nighttime overwater routing preference beyond the existing midnight to 6:00 AM period.

Each of the five alternatives was evaluated through state-of-the-art computer modeling. Comparisons between the various improvement alternatives and the No Action Alternative show the reduction in delay levels and environmental impacts that would be produced with each improvement package. The delay analysis is based on detailed simulations of aircraft operations at Logan, including the flow of aircraft in surrounding airspace, the selection and utilization of various runway configurations, and the movement of arriving and departing aircraft between gates and runways on the airport taxiway system. The analytical approach is described in Section 4.4, and it provides a direct linkage between the models that calculate delays and the models that measure environmental impacts.

Peak Period Pricing was not recommended for immediate implementation as part of the Preferred Alternative. However, Massport does recognize the delay reduction benefits associated with this demand management strategy under potential future conditions of airline over scheduling. As part of the Final EIR, the Secretary instructed Massport to conduct additional analyses to provide a more thorough evaluation of Peak Period Pricing. Section 4.5 describes these three analyses.

First, Massport defines the overscheduling conditions that would lead to implementation of Peak Period Pricing, and designs a monitoring system to determine when these conditions will materialize. Next, a tightly crafted exemption program is developed to protect “greatly affected communities” from losing connections to the national air transportation system. Finally, the section discusses the potential for alterations in the regional airline fleet mix at Logan and/or increased utilization of alternative regional airports that may result from Peak Period Pricing.

In Section 4.6, the results of the airfield delay and operational analysis are described. This section includes an evaluation of how Logan delays will grow in the future without improvements to the airfield, and demonstrates how the Preferred Alternative will limit the growth in delays. The delay analysis has been expanded to include 1998 operating conditions at Logan. This analysis quantifies the current level of Logan delays and identifies the delay reduction benefits that would have been realized if the Preferred Alternative had been available in 1998.

In Section 4.7, operational and delay results for all improvement alternatives with the 37.5M High RJ Fleet are presented. While the 37.5M High RJ Fleet analysis modeled regional jet use of Runway 32 based on the regional jet utilization estimates from an independent FAA analysis, a range of assumptions regarding regional jet use of Runway 32 was also tested. This section also discusses the effect of restricting the use of Runway 32 to northwest wind conditions only. The analysis of various wind restrictions using the 37.5M High RJ Fleet is presented, and the impacts of a restriction on delays, runway use and PRAS performance are discussed.

4.2 Historic Conditions, Recent Trends, and Forecast Passengers and Operations

This section describes the various passenger and operations scenarios that were used in the analyses of the Airside Project Draft EIS/EIR and this Supplemental DEIS/FEIR. Historic and current conditions are described, recent trends are analyzed, and the future forecast scenarios are presented. The development of the 37.5M High RJ Fleet is explained in detail, and the issue of induced demand is also addressed.

4.2.1 Historic Conditions

In the Airside Project Draft EIS/EIR, modeled delay and environmental analyses were presented based on 1993 Logan activity levels and five future operating scenarios. In many instances, 1993 was referred to as the base year because it provided historic context for the analysis presented in the Airside Project Draft EIS/EIR. The EOEA Certificate requested that Massport clarify the use of 1993 in the airside analysis and, if appropriate, provide more current information to supplement the base year analysis.

It is important to understand that the recommendations advanced by Massport in the Airside Project Draft EIS/EIR were based on the comparative delay reduction, environmental, and economic impacts of the various improvement alternatives under the various future operating scenarios. Benefits and impacts were determined through comparisons of each improvement alternative (Alternatives 1, 1A, 2, and 3) with Alternative 4 (the No Action Alternative). In this regard, Alternative 4 represented the effective "base case" under each future operating scenario.

The year 1993 was a peak year for small aircraft operations at Logan Airport, and the demand profile exhibited a relatively high degree of hourly peaking compared to the current profile. It was originally chosen since it represented the most recent data available at the beginning of the Logan Airside Improvements Feasibility Study. It also illustrated operational and environmental conditions during a period of airline overscheduling and high delays. To supplement the 1993 historic analysis, 1998 conditions have been examined in this Supplemental Draft EIS/Final EIR to provide a more recent point of reference for the operational and environmental results. While 1998 exhibited a level of overall demand similar to that in 1993, the 1998 operations exhibited less hourly peaking and included fewer non-jet aircraft. In addition to providing an updated historic context, 1998 conditions

were also analyzed to determine the delay reduction benefits that would have been realized had the Preferred Alternative been implemented in 1998.

4.2.2 Recent Trends

The forecasts presented in the Airside Project Draft EIS/EIR were developed in 1995 at the beginning of the Airside Project. Since these forecasts were developed through the analysis of historic trends and expected future conditions at a particular point in time, it is appropriate to examine recent trends to ensure that the forecasts of future activity still encompass a reasonable range of future scenarios. There were three key developments in the last six years that could impact future activity at Logan:

- Passenger growth at Logan has slowed due to service expansion at New England's regional airports.
- Regional jet aircraft have entered the fleet and services have expanded rapidly.
- Logan's demand profile has become less peaked as airline schedules have smoothed and spread out more evenly over the day.

4.2.2.1 Slower Passenger Growth

Logan passenger growth has slowed significantly, averaging 2.4 percent per year since 1995 and growing only 1.3 percent from 1999 to 2000. This can be compared to the average annual growth rate of 3.1 percent between 1980 and 2000. As explained in Chapter 2 of this Supplemental DEIS/FEIR, this slower growth is primarily due to air service expansion at New England's regional airports. In October 1996, Southwest Airlines entered the New England market, opting to serve Providence (and later Manchester) instead of Logan Airport. This air service expansion and the introduction of competitive fares have resulted in significant growth at both Manchester and Providence. In addition, increased efforts to market the regional airports and the introduction of air travel alternatives, such as Amtrak's Acela service to New York, have also helped develop regional transportation options for New England travelers. This regionalization has effectively dampened Logan's passenger growth rate to a level below that expected when the forecasts for the Airside Project Draft EIS/EIR were originally developed.

4.2.2.2 Rapid Growth in Regional Jets

Regional jets were just entering service when the Airside Project Draft EIS/EIR forecasts were finalized, and while the fleet forecasts accounted for growth in regional jets, they did not anticipate how quickly or extensively airlines would incorporate regional jets into their fleets. In October 1995, there were only 340 regional jets in service worldwide, but by October 2000, carriers had over 1,100 regional jets in service and almost 2,600 on order or option. These regional jets are now serving Logan, and have represented the fastest growing segment of Logan flight demand in recent years.

Logan's regional airlines have traditionally operated non-jet aircraft and have served markets within 400 miles of Boston. The regional jet has expanded the radius of

destinations accessible with small aircraft to approximately 1,000 miles and permitted new nonstop service in medium volume markets such as Richmond, Norfolk, Greensboro, Nashville, Indianapolis, and others. These regional jets have also allowed carriers such as American and Delta to develop competitive jet service patterns in high-volume markets dominated by other carriers. A prime example is the Boston-Philadelphia market, where both American and Delta have initiated high-frequency regional jet services in competition with US Airways (which provides 17 daily round trips with full-size jets).

4.2.2.3 Smoother Demand Profile

The third development that may impact future activity is the smoothing of Logan's demand profile. Figure 4.2-1 shows how the shape of Logan's demand has changed over the last five years. While there have been a number of changes in the characteristics of Logan's demand, the flatter profile can be attributed to three main factors:

- Increased off-peak activity with less activity during the peak;
- Increased frequencies in jet markets; and
- The decline in Logan non-jet activity.

Over the past several years, airlines have increased their off-peak activity at Logan, with a significantly higher percentage of arrivals and departures occurring in the early morning and late evening (see Table 4.2-1). The total growth between 1995 and 2000 was 56 scheduled weekday operations; however, all of that growth occurred in the early morning and late night hours. Early morning operations grew by over 25 percent, with much of the growth in short-haul East Coast markets such as Philadelphia and New York. Over 80 percent of that growth occurred between the hours of 6:00 AM and 8:00 AM. Late-night operations grew by a similar amount, with increases in a wide range of medium- and long-haul markets. Operations during the daytime periods, and even during the peak afternoon period, declined even as the total operations increased, and this pattern was observed in all scheduled market sectors: North American Jet, International Jet, and Non-Jet.

Figure 4.2-1
Comparison of August Weekday Peaking Patterns – 1995 vs. 2000

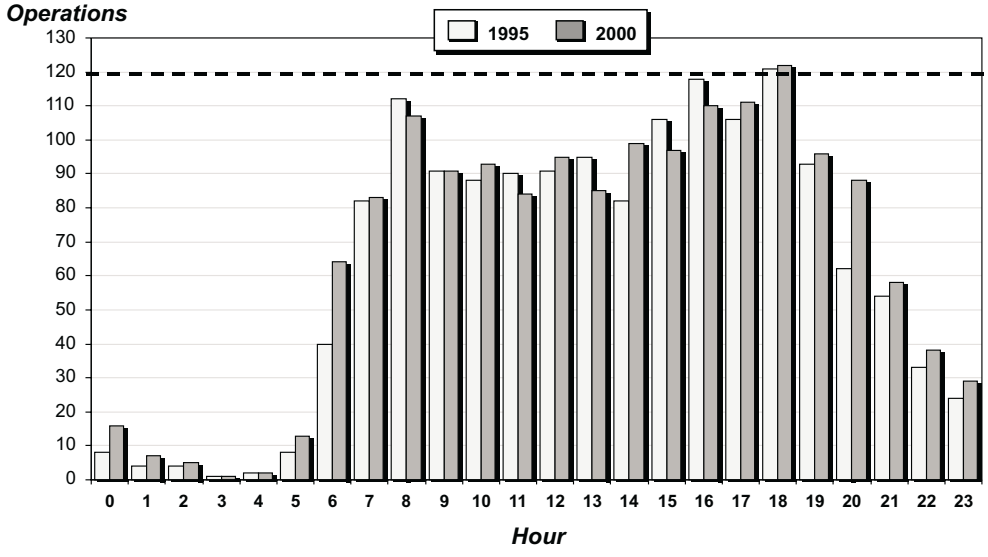

Table 4.2-1
Scheduled August Weekday Passenger Operations by Period: 1995 vs. 2000

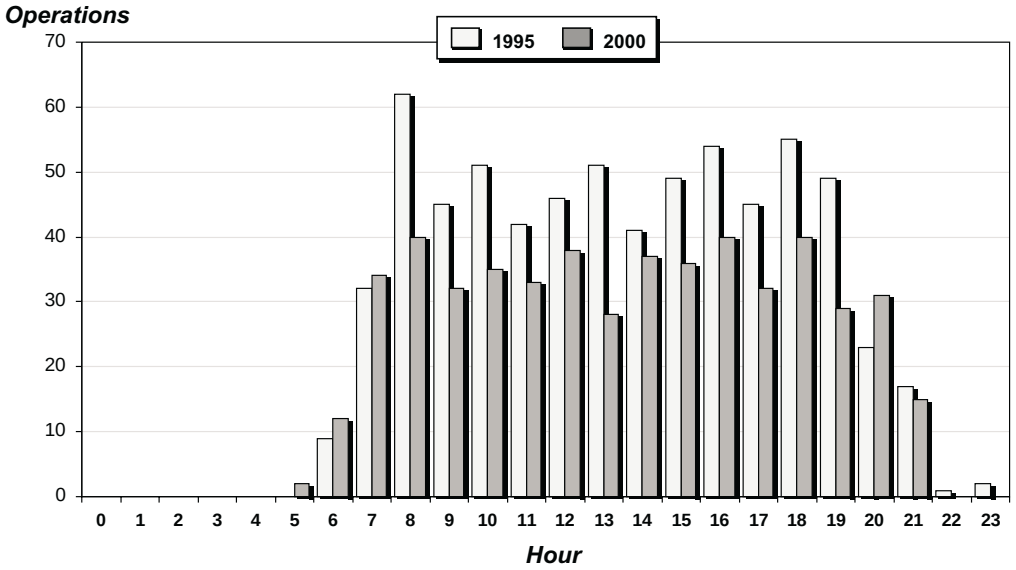
	Operations			Percentage	
Period	1995	2000	Change	1995	2000
Midnight – 4:00 AM	3	15	12	0.2%	1.1%
4:00 AM – 8:00 AM	106	134	28	7.8%	9.4%
8:00 AM – 12:00 PM	356	345	(11)	26.1%	24.3%
12:00 PM – 4:00 PM	352	349	(3)	25.8%	24.5%
4:00 PM – 8:00 PM	404	396	(8)	29.6%	27.8%
8:00 PM – Midnight	145	183	38	10.6%	12.9%
Total	1,366	1,422	56	100.0%	100.0%

Source: OAG Schedule Tapes

Along with the increased off-peak activity, increased jet frequencies also tend to flatten the demand profile by providing a steady level of operations all day long. In August 1995, Logan had non-stop service to 61 jet destinations with an average frequency of 5.7 round trips per weekday. In August 2000, Logan had nonstop service to 64 jet destinations with an average frequency of 7.1 round trips per weekday. Furthermore, the average frequency to Logan's top ten jet destinations increased from 17.8 daily round trips to 21.4 daily round trips. As frequencies to an individual destination increase, operations tend to become less concentrated during the peak periods.

The changes in Logan's non-jet fleet have also played a role in flattening the demand profile. Figure 4.2-2 compares the scheduled non-jet activity at Logan in 1995 and 2000. Non-jets have historically been the most peaked market segment at Logan, but over the last several years, non-jet activity at the airport has declined in both total and peak hour activity. Logan served 40 non-jet destinations in August 1995 but only 27 non-jet destinations by August 2000. Non-jet carriers pulled out of markets such as Hartford, Lebanon, and Manchester, even though each had at least six daily round trips in August 1995. In addition to the market reduction, the number and distribution of non-jet operations has changed. In August 1995, Logan averaged 49 hourly non-jet operations between 8:00 AM and 8:00 PM with a peak hour level of 62 operations. By August 2000, Logan averaged only 35 hourly non-jet operations over the same twelve-hour period, reaching a peak level of only 40 hourly operations.

Figure 4.2-2
August Weekday Scheduled Non-Jet Demand: 1995 vs. 2000



4.2.2.4 Summary of Recent Trends

It is reasonable to expect that the recent trends observed at Logan will continue into the future: 1) slower passenger growth, 2) increased regional jet activity, and 3) a smoother demand profile. Ongoing efforts towards regionalization will cause passenger growth to continue at a slower rate, consistent with the growth predicted in the FAA Terminal Area Forecasts. Regional jets have operational and economic advantages for serving medium density markets within 1,000 miles and for allowing competitive entry into high-volume markets. These aircraft are therefore likely to play a significant role for Logan carriers well into the future. Finally, the less-peaked demand is expected to continue. In general, peaks tend to spread as demand grows and frequencies increase. Also, the move from turboprop aircraft to regional jets ensures a continued decline in the Logan market segment with the most peaked demand.

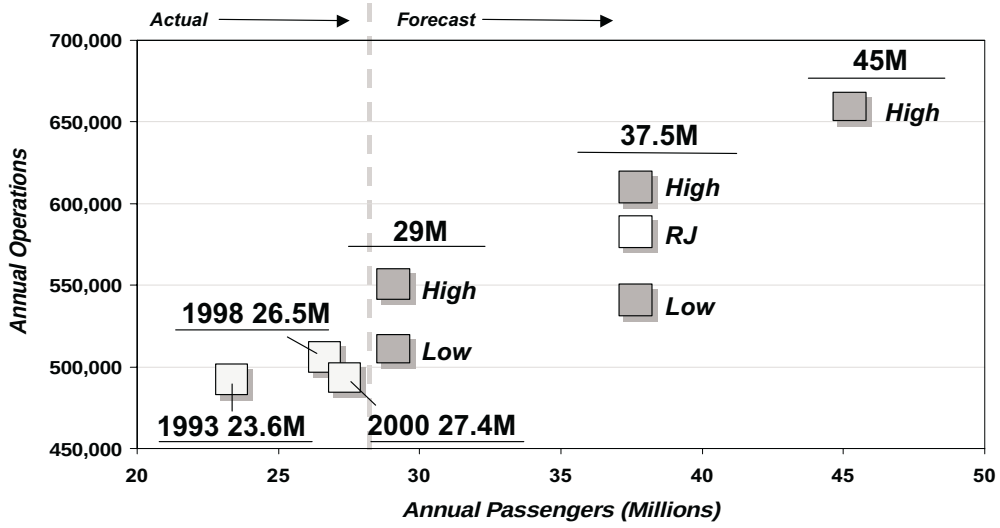
The forecasts presented in the Airside Project Draft EIS/EIR covered a wide range of passenger levels and fleet mixes, and they continue to represent an appropriate range of future activity for the purposes of this analysis. However, in light of the more recent trends and the likelihood that they will continue, an additional future scenario was developed for this Supplemental DEIS/FEIR to ensure that all reasonable forecast conditions were addressed.

4.2.3 Passenger Forecasts

In order to evaluate the Airside Project Alternatives under a variety of future scenarios, Massport has developed a range of near- and long-term passenger forecasts. As shown in Figure 4.2-3, three different passenger volumes (29 million, 37.5 million, and 45 million) were evaluated for a range of operations levels. Based on the slower passenger growth due to regionalization discussed in the previous section, the airport is expected to reach 29 million passengers within a few years, 37.5 million passengers around 2015, and 45 million passengers sometime after 2020. These projections reflect more conservative growth than the forecasts presented in the Draft EIS/EIR, which assumed that Logan would reach 29 million passengers in 1999 and 37.5 million by 2010.

While the time frames associated with the forecasts in the Airside Project Draft EIS/EIR have been adjusted to reflect the growth at regional airports, the aircraft fleet forecasts, the delay modeling, and the environmental analyses associated with the passenger levels are still appropriate near- and long-term term scenarios. By adjusting the time frame associated with each of the passenger levels rather than adjusting the passenger levels themselves, the 29 million, 37.5 million, and 45 million passenger scenarios in this Supplemental DEIS/FEIR can still be compared with similar scenarios examined in other Logan analyses.[1] Furthermore, these revised forecast dates are consistent with the FAA's most recent Terminal Area Forecasts which project that Logan will handle 33.6 million passengers in 2010 and 37.1 million in 2015. By examining historic 1993 conditions, recent demand (1998), and near- and long-term planning values of 29, 37.5, and 45 million passengers, the airside analysis has incorporated a comprehensive set of past, present, and future demand levels that provide a broad context for the evaluation of the proposed Airside Project improvement alternatives.

Figure 4.2-3
Logan Airside Passenger and Fleet Forecasts



1 Previous Logan Airport Generic Environmental Impact Reports (GEIRs) and Annual Updates, as well as the 1999 Environmental Status and Planning Report (ESPR), published in December 2000, have all examined future passengers levels of 29M, 37.5M, and/or 45M.

4.2.4 Operations Forecasts

While the various passenger forecast scenarios represent near- and long-term passenger demand for airport services, the aircraft operations forecasts tie that demand to the airside modeling process. The forecast variables that impact the operations and environmental analysis include:

- The demand level in terms of aircraft operations;
- The mix of aircraft types; and
- The demand profile, or the distribution of operations by hour across the operating day.

The Airside Project Draft EIS/EIR included six forecasts of future activity (five of which were carried through the detailed analysis process)[2], with a Low Fleet and High Fleet operations scenario for each of the three forecast passenger levels (29M, 37.5M, and 45M). These Low Fleet and High Fleet scenarios represent two different ways that a single future passenger volume could be satisfied. The Low Fleet forecasts reflect the assumption that commuter aircraft will make up a smaller share of the fleet serving Logan, while the High Fleet forecasts reflect the greater use of small aircraft and the resulting need for more flights to carry a given number of passengers.

To incorporate the recent Logan trends discussed previously in this section, an additional analysis scenario, referred to as the 37.5M High RJ Fleet, has also been developed. The 37.5M High RJ Fleet assumes slow passenger growth due to regionalization, reaching 37.5 million passengers circa 2015. To reflect the smoother demand profile, the hourly distribution of demand is based on the current demand profile rather than the more peaked profile from FY1995 that was used to develop the profiles for the Airside Project Draft EIS/EIR forecasts. The 37.5M High RJ Fleet also assumes significant growth in regional jet activity.

By developing a forecast that represents relatively high regional jet growth, the operational and environmental impacts of regional jets are bounded by the lower level of regional jets in the Airside Project Draft EIS/EIR forecasts and by the higher level in the 37.5M High RJ Fleet. Table 4.2-2 presents the full range of operations forecasts analyzed in the Airside Project. These alternatives are designed to ensure that the airfield analysis includes an appropriate range of future conditions at Logan. The delay results for the 29M High, 37.5M Low and 45M High Fleets are summarized Appendix C, while the operational results for the 29M Low, the 37.5M High, and the 37.5M High RJ Fleets are presented in the following sections.

▼

2 The 45M Low Fleet forecast was initially evaluated with the runway capacity and delay models but was not carried through the detailed taxiway and environmental analysis process because of its similarity to the 37.5M High Fleet scenario.

Table 4.2-2
Logan Near- and Long-Term Operations Forecasts

Forecast Scenario (Passenger Level and Fleet)	Aircraft Operations
29M Low	510,000
29M High	552,000
37.5M Low	543,000
37.5M High RJ	585,000
37.5M High	608,000
45M Low	580,000
45M High	656,000

Notes: The 37.5M High RJ Forecast was not analyzed in the Airside Project Draft EIS/EIR and has been added as an additional scenario in this Supplemental Draft EIS/Final EIR.
The 45M Low operations forecast was initially evaluated with the runway capacity and delay models, but was not carried through the detailed taxiway and environmental analysis process because of its similarity to the 37.5M High Fleet scenario.

4.2.4.1 Near-Term Planning Forecasts

The development of the near-term 29M Low and High Fleets is explained in detail in Chapter 4 and Appendix E of the Airside Project Draft EIS/EIR. Table 4.2-3 compares the major features of the 29M High and Low Fleet operations scenarios, but this Supplemental DEIS/FEIR focuses on the 29M Low Fleet for the operational and environmental analyses. Both alternatives are based on 29 million annual passengers, but non-jet aircraft carry 11 percent of the passengers in the High Fleet scenario compared to 9.5 percent in the Low. This difference, combined with a higher average load factor in the Low Fleet scenario, increases the average number of passengers per operation in the Low Fleet scenario and allows Logan carriers to handle the same number of passengers with 42,000 fewer flights.

Table 4.2-3
Near-Term Operations Forecasts

	29M Low	29M High
Operations		
Mainline Jet	259,000	264,000
Regional Jet	15,000	3,000
Regional Non-Jet	197,000	246,000
Subtotal - Passenger Operations	472,000	513,000
Cargo	13,000	13,000
General Aviation	25,000	25,000
Total	510,000	552,000
Distribution of Passengers		
Jet (Mainline and Regional Jets)	90.5%	89.0%
Regional Non-Jet	9.5%	11.0%
Average Passengers per Flight		
Jet (Mainline and Regional Jets)	96.4	95.6
Regional Non-Jet	13.6	12.5

4.2.4.2 Long-Term Planning Forecasts

The discussion in this Supplemental DEIS/FEIR focuses on the 37.5M High Fleet and the 37.5M High RJ Fleet, but all of the long-term forecasts are presented in Table 4.2-4 for comparison purposes (the 37.5M Low, 37.5M High, and 45M High Fleets were described in Chapter 4 and Appendix E of the Airside Project Draft EIS/EIR). The 37.5M High RJ scenario was developed using the same basic methodology used for the other fleets, but it incorporates the recent Logan trends towards slower passenger growth, increased regional jet activity, and less-peaked demand. The major forecast assumptions for the 37.5M High RJ fleet are summarized below:

- Airport passenger traffic was assumed to grow at 2.1 percent per year, reaching 37.5 million passengers by 2015, consistent with the FAA Terminal Area Forecasts.

- Operations were forecast to grow at 1.3 percent per year, resulting in an operations level between the 37.5M Low and High Fleet scenarios.

  - Regional jet aircraft were projected to replace most turboprops and a portion of conventional narrowbody jets with less than 120 seats. High growth in regional jet operations was assumed so that the fleet tests an appropriate upper range of regional jet activity.

  - The general aviation and cargo forecasts were updated to reflect recent Logan trends. General aviation operations were forecast to reach an annual level of 41,000 operations since Logan handled approximately 40,000 general aviation operations in fiscal year 2000. Cargo operations were forecast to grow at two percent per year based on historic growth trends at the airport.

Table 4.2-4 compares the four alternative long-term forecasts. The 37.5M High Fleet requires 608,000 annual operations to handle 37.5 million passengers, while the 37.5M Low Fleet requires only 543,000 annual operations due to the higher average number of passengers per flight. The 37.5M High RJ scenario represents a mid-range 37.5 million passenger scenario in terms of both total operations and passenger operations, but the mix of passenger operations varies dramatically when compared to the 37.5M Low and High Fleets.

The Low and High scenarios have roughly three times as many non-jet operations as the High RJ Fleet, while the High RJ scenario offsets this difference with a much greater level of regional jet operations. While this seems like a large difference, the total number of annual regional carrier operations in the 37.5M High RJ scenario, including both regional non-jets and regional jets, is 249,000. This falls between the 37.5M Low value of 223,000 and the 254,000 regional carrier operations in the 37.5M High scenario. Because of the large number of regional jets in the High RJ scenario, a much higher percentage of passengers travel on jet aircraft; however, the number of passengers per jet operation is significantly lower.

Table 4.2-4
Long-term Operations Forecasts

	37.5M Low	37.5M High RJ	37.5M High	45M High
Operations				
Mainline Jet	281,000	279,000	310,000	335,000
Regional Jet	24,000	184,000	19,000	25,000
Regional Non-Jet	199,000	65,000	235,000	253,000
Subtotal - Passenger Operations	505,000	528,000	564,000	612,000
Cargo	13,000	15,000	19,000	19,000
General Aviation	25,000	41,000	25,000	25,000
Total	543,000	585,000	608,000	656,000
Distribution of Passengers				
Jet (Mainline and Regional Jets)	91.5%	97.5%	90.9%	91.0%
Regional Non-Jet	8.5%	2.5%	9.1%	9.0%
Average Passengers per Flight				
Jet (Mainline and Regional Jets)	111.9	78.7	103.2	113.6
Regional Non-Jet	16.0	14.2	14.5	16.0

While Logan has been following a Low Fleet development path since 1993/94, the recent growth in regional jets and carrier plans to develop individual regional carrier networks may suggest a shift towards a High Fleet scenario. To capture the full range of probable near- and long-term operating conditions at Logan, the operational analysis described in this Supplemental DEIS/FEIR focuses on the No Action and Preferred Alternative analysis of the 29M Low and 37.5M High scenarios. This Supplemental Draft also includes the complete analysis of the 37.5M High RJ Fleet for all improvement alternatives. Chapter 4 of the Airside Project Draft EIS/EIR compared the operating benefits of all improvement alternatives against the full range of future fleet scenarios, and these comparisons are also summarized in Appendix C of this Supplemental DEIS/FEIR.

4.2.5 Induced Demand

Some of the public comments received on the Airside Project Draft EIS/EIR suggest that implementation of unidirectional Runway 14-32 and the other proposed airside improvements will stimulate an increase in passenger traffic and/or aircraft operations at Logan Airport. However, for a series of reasons, the Preferred Alternative will not induce additional aircraft operations or passenger demand at Logan.

Implementation of the Preferred Alternative, and specifically the construction of unidirectional Runway 14/32, does not increase Logan's normal airfield capacity of approximately 120 operations per hour. This capacity is available at Logan approximately 80 percent of the time. Runway 14/32 will allow Logan to maintain this capacity during

periods of strong northwest winds that now require controllers to operate on two, and sometimes only one runway, compared to Logan's typical three-runway configurations. Runway 14/32 will increase Logan's reliability, but will not increase the airport's normal operating capacity.

The situation at Logan contrasts with runway projects at other airports where a new runway can increase airfield capacity, sometimes by a significant margin. In many cases, new runways are constructed with the specific objective of increasing capacity to accommodate higher levels of demand. For example, when Dallas-Ft. Worth International Airport commissioned a new runway (35R/17L) in 1996, its hourly arrival capacities increased from 102 to 146 under VFR conditions, and from 66 to 108 under IFR.

In addition, Logan is not a connecting hub airport and has no single dominant carrier. A connecting hub operation depends on efficient connections between arriving and departing flights. The hub carrier has a vested interest in maintaining schedule reliability, and has the ability to directly influence delays through its own scheduling decisions, due to the high percentage of total airport activity that its own flights represent. This is not the case at a highly competitive airport such as Logan.

Logan is principally an O&D airport, not a connecting hub facility, and no single airline at Logan maintains a dominant share of total airport flight activity. As a result, the scheduling decisions of any individual carrier will have only limited impact on overall airport delays, and it is therefore unlikely that carriers are currently suppressing flight schedules due to delays at Logan. Comparatively low passenger load factors at Logan provide further evidence that flight schedules are not being artificially depressed by delay conditions.

Unlike the Dallas-Ft. Worth runway project and others, the proposed unidirectional Runway 14/32 will not increase Logan's normal operating capacity. It will, however, substantially reduce the delays that now occur during northwest wind conditions. Preventing these delays will represent a benefit to the passengers and airlines that currently experience them. However, these wind conditions and the associated aircraft delays are not regular or predictable, and cannot be readily anticipated by airlines or passengers. Therefore, preventing these delays will not stimulate growth in Logan passenger demand above and beyond the rates that would have occurred absent proposed Runway 14/32.

Total door-to-door trip time for an average Logan passenger is more than 6 hours, including airport access and egress, waiting time before the flight, and actual flight time. The average delay savings that would result from the implementation of the Preferred Alternative are not of a magnitude that would induce passengers to make trips that they would otherwise not have taken.

For the reasons described above, the Preferred Alternative will not result in induced passenger or flight demand at Logan. Instead, growth in demand will be principally driven by local and national economic conditions and by competition and pricing within the airline industry. In any event, the broad range of forecasts considered in the Airside Project operational and environmental analyses encompass the impacts that would be associated with any growth scenario.

4.3 Preferential Runway Advisory System (PRAS)

Logan's Preferential Runway Advisory System (PRAS) goals underlie the delay and environmental modeling of the No Action (Base Case) and Action alternatives presented in the Airside Project Draft EIS/EIR. The EOEA Secretary requested that Massport broaden the discussion of PRAS in the Final EIR to demonstrate that the PRAS objectives provide a valid basis for the operational and environmental analyses. Logan's PRAS program is a set of recommended targets for FAA runway assignments. The objectives of PRAS are: a) to reduce noise exposure for the most highly impacted communities (i.e., those within the 70 and 75 dB DNL contours) by distributing noise impacts in accordance with runway utilization goals established jointly by Massport, the FAA, and community representatives; (b) to provide short-term relief from continuous aircraft operations over neighboring communities; and (c) to maximize use of overwater aircraft routings.

This section responds to the comments of the Secretary and other reviewers by presenting the historical context of the development of PRAS. This section also examines current and historic land use patterns and residential densities among the affected communities to determine whether they have remained relatively unaltered since the PRAS Program was initially developed. Finally, this section reviews historic levels of PRAS achievement to support its utility as the basis for projecting future runway utilization at Logan.

4.3.1 History of Preferential Systems at Logan

In 1968, the FAA authorized formal and informal runway use programs for noise relief. Following FAA authorization, preferential runway procedures with simple priority selection methods were initiated at Logan. Since that time, Massport, in conjunction with the FAA and representatives of surrounding communities, has continued to study and refine the goals and methodology for implementing PRAS.

Between 1980 and 1983, formal PRAS goals were established by the PRAS Advisory Committee. This committee was composed of representatives from Massport, the FAA, airlines, and 12 neighboring communities. The first computerized PRAS system was installed at Logan in 1983. Since that time, two major enhancements to the PRAS computer

system have been implemented at Logan: Enhanced PRAS in 1993 and Revised PRAS in 1996. These enhancements were designed to improve the conformance and use of the PRAS system by FAA controllers, and ultimately lead to improved achievement of the PRAS goals. As described later in this chapter, the PRAS enhancements have been accompanied by improvements in PRAS conformance at Logan.

4.3.2 PRAS Objectives and Goals

The PRAS Advisory Committee established the objectives of the system at the beginning of the original development between 1980 and 1983:

- Reduce noise exposure on populations residing in the most highly impacted communities, without significantly increasing the impact on any populated area within the day-night sound level (DNL) contour of 65 dB; and

- Maximize the use of runway 15R for overwater departures and 33L for overwater arrivals.

The PRAS goals are one of the criteria used for runway selection. The committee determined that the PRAS goals should provide a more equitable distribution of aircraft noise over the long-term (i.e. annually), and offer short-term relief from excessive operations over individual neighborhoods.

4.3.2.1 Long-Term Goals

To quantify the long-term noise goals, the committee reached a consensus on annual runway end use percentages in terms of equivalent jet operations. Equivalent operations include all daytime (7:00 AM to 10:00 PM) jet flights, plus nighttime (10:00 PM to 7:00 AM) jet operations multiplied by a factor of ten. This is consistent with the methodology for computing DNL, in which 10 dB are added to nighttime operations. The annual runway end use goals are shown in Table 4.3-1.

PRAS maintains a continuous count of the jet operations on each runway end for the most recent twelve-month period. Whenever a new recommendation is needed, it checks the wind and weather conditions and the expected demand level, and then identifies runway combinations which are available to meet these requirements. If there is more than one choice available, the combination that will produce the best match with the annual and short-term goals is recommended.

Table 4.3-1
PRAS Goals for Effective Jet Aircraft Runway Use

	PRAS Effective Usage Goals	
Runway End	**Arrivals**	**Departures**
4R/L	21.1%	5.6%
9	0.0%	13.3%
15	8.4%	23.3%
22L/R	6.5%	28.0%
27	21.7%	17.9%
33	42.3%	11.9%

Note: PRAS goals are stated in terms of effective jet operations which exclude non-jet flights, but which multiply each nighttime (10:00 PM to 7:00 AM) operation by a factor of 10. Each nighttime jet operation is therefore equivalent to ten daytime jet operations.

4.3.2.2 Short Term Goals

In order to provide temporary relief to neighborhoods impacted by regular overflights during single or multi-day periods, the PRAS Advisory Committee established two short-term goals for the system in addition to the annual goals:

- Provide relief from excessive dwell (more than seven hours of operations over a given area during any day between the hours of 7:00 AM and midnight); and

- Provide relief from excessive persistence (more than 23 hours of operations over an area between 7:00 AM to midnight during a period of three consecutive days).

In contrast to the annual goals that count the number of equivalent operations on a runway, dwell and persistence are measured by the number of hours that a given area is subjected to jet aircraft overflights. The PRAS Advisory Committee designated eight runway combinations for computing the effects of dwell and persistence on the communities. The dwell and persistence areas are defined by community as shown in Table 4.3-2.

Table 4.3-2
PRAS-Defined Dwell and Persistence Areas

Runway	Areas
4L&R Arrivals	South Boston (Farragut Street), Dorchester, Quincy, Milton, and Braintree
33L Arrivals	Boston Harbor, Hull
15 Departures	Boston Harbor
22 L&R Departures	South Boston (Farragut Street), Boston Harbor
27 Departures	South Boston (Fan Pier), Roxbury, and Jamaica Plain
4L&R Departures Plus 22L&R Arrivals	East Boston (Bayswater, Orient Heights), Winthrop (Court Road), and Revere
9 Departures plus 27 Arrivals	Winthrop (Point Shirley), and Boston Harbor
33 Departures plus 15 Arrivals	East Boston (Eagle Hill), Chelsea, Everett

4.3.2.3 PRAS Nighttime Routing Preference

One of the primary objectives of the PRAS system is to maximize the use of Runway 15R for overwater departures and 33L for overwater arrivals. While the annual goals alone attempt to maximize these operations, PRAS has additional nighttime preferences. Between the hours of 12:00 AM and 6:00 AM, the noise abatement procedures followed by the FAA controllers specify set runway priorities. Whenever possible, controllers will simultaneously use 33L for arrivals and 15R for departures. This opposite direction configuration is available only under VFR conditions with clear runways, and long separation requirements limit capacity; however, this configuration directs all operations over the water, reducing noise impacts and increasing PRAS goal achievement. Dwell and persistence are ignored at night so that this configuration can be used extensively, and when weather permits, controllers typically use this configuration for the full six-hour period.

4.3.3 Continued Validity of PRAS Goals

Although PRAS's long- and short-term goals were first developed nearly 20 years ago, land use patterns and population growth during the intervening years provide no evidence to support any change in the established preferences.[3] For example, Figures 4.3-1 and 4.3-2 depict major land use categories within the project study area at the approximate time when the goals were established and for a more recent period, respectively.

3 In 2000, the Citizens Advisory Committee (CAC) voted to withdraw its support of the PRAS goals.

Figure 4.3-2

1991 Land Use

Source: Harris Miller Miller & Hanson

The information was obtained from MassGIS, a state organization that collects land use data and updates when it is feasible. A comparison of the two figures shows there has been little if any conversion to or away from residential use. Thus, the major residential areas that were of concern to the communities and Massport when PRAS goals were first adopted in the early 1980's are still of concern today. There have been no shifts of major residential areas.

Supplementing this information is Table 4.3-3, which shows how residential population within different noise-impacted communities has changed over time. Using US Census data and a single set of noise contours from the Airside Project Draft EIS/EIR to define a fixed area, the table compares the numbers of people, by community, that reside within 5 dB increments of exposure. The earlier population data reflect the distribution of people around Logan when PRAS goals were first adopted; the later population data reflect a more current distribution.

While the counts show a modest overall increase in population within the DNL 60 contour over a ten-year period, the changes do not always occur uniformly by community. What they do show, however, is that no major redistribution of population has occurred. Not one community has changed its ranking relative to the others over the ten-year period. Collectively, these unchanged land use patterns and population distributions support the continued validity of the original PRAS goals.

4.3.4 Historic PRAS Conformance

Statistics on the conformance of the PRAS system have been collected since the original system was installed in 1983. In order to interpret those statistics, it is important to understand the fundamental changes that have occurred in the PRAS system in the 16 years since the original installation.

4.3.4.1 PRAS Revisions

While there have been numerous minor improvements, there are three primary versions of PRAS that have been used at Logan over the years:

- **Original PRAS:** This version of the program, installed in 1983, incorporated the original goals and simple runway selection logic.

- **Enhanced PRAS**: This version of the program, installed in 1993, was designed to try to improve PRAS goal achievement.

- **Revised PRAS:** This version of PRAS, which is currently in use, incorporates automated data input to greatly enhance usability.

Table 4.3-3
Comparison of Population Counts for the 29M Low and the No-Action Alternative Using 1980 and 1990 Census Data[1]

Noise-exposed Community	1980 Census Counts			
	DNL greater than 60 dB	DNL greater than 65 dB	DNL greater than 70 dB	DNL greater than 75 dB
East Boston	25,404	7,235	595	0
Winthrop	12,700	4,686	1,182	155
Chelsea	7,997	2,828	0	0
South Boston	6,215	945	0	0
Revere	5,596	3,669	0	0
Deer Island[2]	499	0	0	0
Everett	215	0	0	0
Total	58,626	19,363	1,777	155

	1990 Census Counts			
	DNL greater than 60 dB	DNL greater than 65 dB	DNL greater than 70 dB	DNL greater than 75 dB
East Boston	26,035	7,117	437	58
Winthrop	11,799	4,291	1,084	199
Chelsea	10,232	3,056	0	0
South Boston	6,010	66	0	0
Revere	5,227	3,001	0	0
Everett	220	0	0	0
Deer Island[2]	0	0	0	0
Total	59,523	17,531	1,521	257

1 Communities are ordered from highest to lowest according to the number of residents within the 60 dB DNL noise contour.
2 Deer Island's prison population was included in the 1980 Census but in light of impacts under 65 dB was never considered a major factor in developing PRAS goals. Its inmates have since been relocated to accommodate the new Boston Harbor wastewater treatment facility.

4.3.4.2 Original PRAS

The original PRAS at Logan was installed in 1983 and was based on conditions that existed in 1981 or before. These conditions included aircraft activity levels and fleet mix, FAA procedures, and technology (both aviation and computer). Although the system represented the state-of-the-art at the time it was designed, the FAA and Massport recognized in the late 1980s that it had limitations.

To be effective PRAS must be able to identify runway configurations that are capable of serving given levels of demand and decide which one among the eligible configurations to recommend. The original PRAS had only limited technical flexibility to perform these tasks effectively. In particular, it was designed with a fixed daily demand schedule from 1980-82

operations, and it had no automatic capability to update this schedule to adjust to the changes in demand that accompanied the large growth in commuter operations.

4.3.4.3 Enhanced PRAS

The enhanced PRAS was installed in 1993 to address the limitations in the original PRAS and to provide flexibility to accommodate changes in airport operations and / or FAA procedures. It was designed as a forward-looking system to assist the FAA in planning operations throughout a shift. It operated 24 hours per day, and provided a choice of recommended eight-hour configuration plans to the FAA operator, who could modify the plan as needed. The enhanced PRAS incorporated an estimate of the controller workload required to change configurations into its planning logic.

Enhanced PRAS was tested for approximately nine months by the FAA in the Logan Control Tower. While Enhanced PRAS addressed many of the concerns the FAA raised about the original system, the new system required controllers to manually enter and continually update data on current weather conditions, weather forecasts, traffic demand, runway closures, and runway surface conditions. This data entry imposed additional controller workload on top of already demanding primary air traffic control activities.

4.3.4.4 Revised PRAS

The current system, revised PRAS, was installed in 1996 to reduce the effort required for controllers to use the system. Revised PRAS was linked to the Systems Atlanta Information Display System (SA-IDS), and the inputs for traffic demand, current weather, weather forecasts, runway closures, and runway conditions were provided automatically. This automated data entry has led to better system conformance and PRAS goal compliance.

4.3.4.5 Historic Achievement of PRAS Goals

This section examines historic PRAS conformance at Logan from three perspectives:

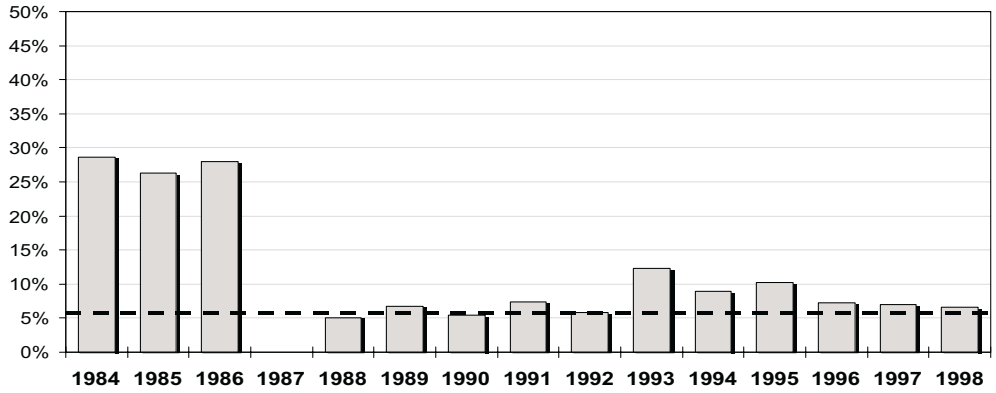
- Individual runway utilization compared to the PRAS annual goals;
- A PRAS performance index that measures the aggregate achievement of annual goals across all runways; and
- Comparisons of historic runway utilization to the predicted usage based on the model.

Historic Utilization of Individual Logan Runways Compared to PRAS Goals

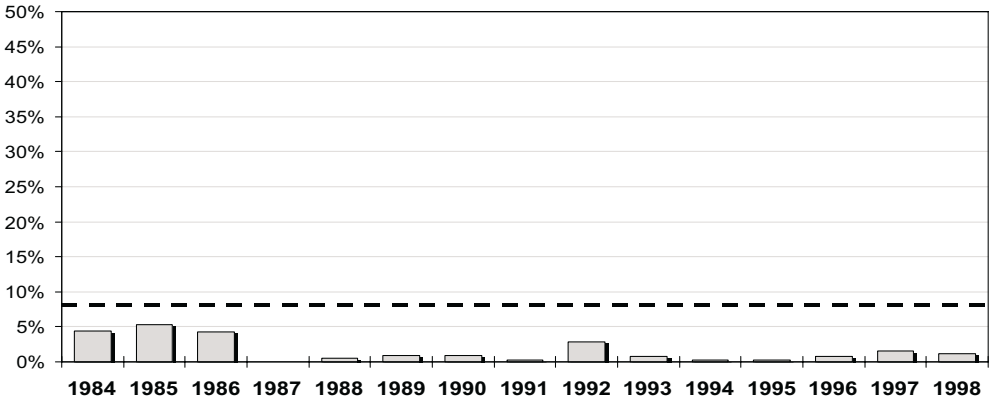
Figures 4.3-3 and 4.3-4 summarize the historic levels of PRAS achievement relative to the annual goals for individual Logan runways from 1984 through 1998. While there is a wide variation in conformance relative to the goals, this is expected due to variations in weather conditions, fleet mix, and FAA operational techniques (i.e., Land and Hold-Short Operations, or LAHSO, on 22L and 27) from year to year. Other factors such as airfield construction and airline scheduling also have an impact. Still, a number of conclusions can be drawn.

Figure 4.3-3
Equivalent Jet Arrival Operations by Runway and Year

Arrive 4 (Goal = 21.1%)



Arrive 15 (Goal = 8.4%)



Arrive 22 (Goal = 6.5%)

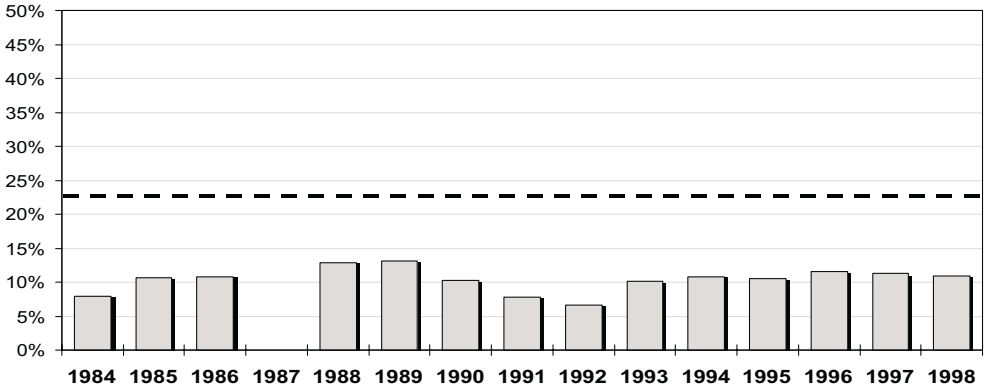

Figure 4.3-4 (Cont'd.)
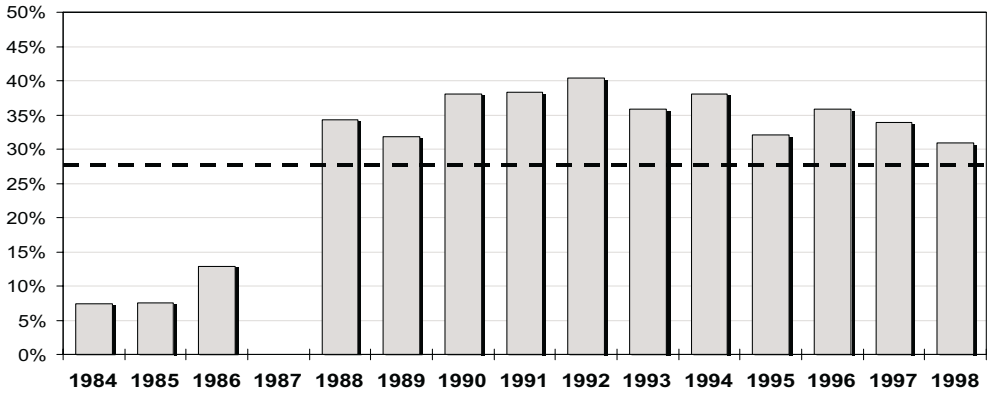
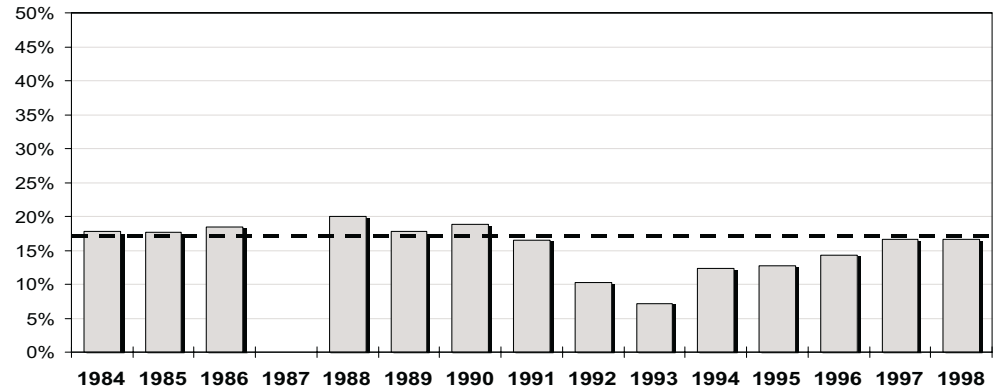
Equivalent Jet Departure Operations by Runway and Year

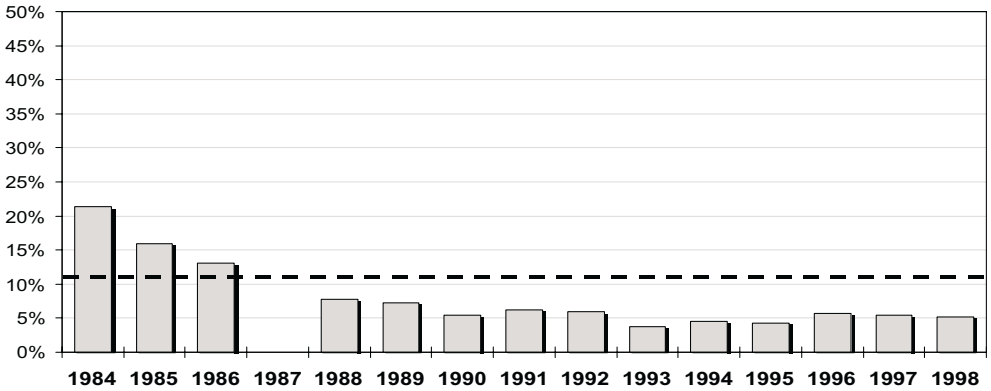
Depart 22 (Goal = 28.0%)



Depart 27 (Goal = 17.9%)



Depart 33 (Goal = 11.9%)



[redacted]

For arrivals, it is clear that Runway 4 arrivals have always exceeded the goal, and that conformance with the goal declines with higher demand and peaking, as in 1993. This is expected since Runway 4 arrivals correspond to the highest capacities at Logan. Conversely, arrivals on Runway 15 and Runway 33 have always been well short of the goals as these runways exhibit lower operational capacities. Since 1988, Runway 27 arrivals have been above the goal whereas they were formerly below it. This change is due to the FAA implementation of land-and-hold-short operations (simultaneous landings on Runway 22L and Runway 27 while departing on Runway 22R), which increased the capacity of the configuration while operating under Visual Meteorological Conditions (VMC).

For departures, Runway 9 departures have always exceeded the goals, due to that runway's simultaneous use with Runway 4L/R arrivals. Runway 22 departures began to exceed the goals in 1988 with implementation of land-and-hold-short operations. Runway 4 and 27 departures have remained near the goals for the most part, but Runway 4 departures increased and Runway 27 departures declined during the highly peaked conditions around 1993. For the past ten years, both Runway 15 and Runway 33 departures (much like the arrivals) have been below the target levels.

Aggregate PRAS Achievement Across All Logan Runways

While it is useful to view the individual runway end use over time, overall PRAS conformance may also be judged by examining all runways simultaneously, especially considering the variability of weather, demand, and other factors. In order to evaluate overall PRAS achievement over time, a PRAS Performance Index (PPI) was developed that represents the performance of all runways relative to the annual goals. The PPI measures deviations[4] from the PRAS goals for each Logan runway, the same measure used in the PRAS selection algorithm to determine the best configuration relative to the annual goals on an ongoing basis. Because the PPI measures differences from the runway utilization goals, lower values represent better PRAS achievement. Figure 4.3-5 presents the PPI relative to the number of total annual Logan operations for the period from 1984 through 1998.

The PPI will tend to increase as operations grow since increasing flight levels can limit controller flexibility in selecting runway configurations. While this is generally true, system enhancements have helped improve PRAS achievement, despite growing Logan activity levels, as described below:

- When PRAS was originally installed, there was an immediate improvement in goal conformance during the first few years.
- From 1988 through 1992, the original PRAS became less effective (for reasons explained above), and PRAS goal deviations increased along with airport operations.
- Performance relative to the goals has improved considerably since then with the installation of enhanced PRAS in 1993 and revised PRAS in 1996.

These changes in PRAS performance demonstrate that the FAA is striving to achieve the best possible PRAS goal achievement and has made considerable progress in this area.

4 Calculated as the sum of the squared deviations from the stated PRAS goals.

PRAS Performance Index

Notes: 1987 PRAS performance information not available; PPI = Sum of squared deviations

4.3.4.8 Historic PRAS Performance Compared to Model Predictions

The operational and environmental analyses conducted for the Airside Project Draft EIS/EIR and the Supplemental Draft EIS/Final EIR do not assume perfect achievement of PRAS goals. Instead, the DELAYSIM model selects runway configurations based on hour-to-hour demand levels and the capacities of available runway configurations. It is only when more than one runway combination has sufficient capacity to accommodate flight demand that the PRAS long- and short-term goals are considered in the runway selection process.

In order to evaluate how closely DELAYSIM would have simulated historic runway utilization patterns, Logan flight activity patterns between 1991 and 1998 were modeled using reported weather patterns for each individual year. Figures 4.3-6 and 4.3-7 show the historic utilization of each Logan runway by year, and compare this to the predicted results based on DELAYSIM modeling. The comparative analysis indicates that for most Logan runways, the differences between actual and simulated utilization are small, and that the margin between actual and simulated runway usage has narrowed over time. This comparison supports the use of PRAS goals within the operational analysis for environmental review purposes.

4.3.5 PRAS Reporting and Monitoring

Comments on the Airside Project Draft EIS/EIR and the May 7, 1999 EOEA Certificate requested that quarterly and annual PRAS achievement reports be developed, that the distribution list be broadened, and that results be reported in the GEIR/ESPR. Design of monitoring protocols was also requested. Massport currently monitors PRAS performance at Logan and reports results both internally, to the FAA, and to requesting members of the general public. This section describes the PRAS Monitoring System developed by Massport and describes how PRAS monitoring and reporting will be expanded in response to these requests.

4.3.5.1 Current PRAS Reporting and Monitoring

The PRAS computer system was designed to track a number of statistics and to generate reports comparing Logan runway utilization patterns to the PRAS goals. The PRAS monitoring program produces seven regular reports on PRAS performance, which are described in greater detail below:

- **Monthly Operations**: This report presents the average daily jet arrivals and departures by runway and time of day for any given month. It also shows average day, night, equivalent, and total operations by month relative to the annual PRAS goals.
- **Monthly Utilization**: This report shows the hours and maximum consecutive hours of arrival and departure runway use for each day of a given month. It presents the total monthly and average daily utilization of runways in terms of hours of jet arrivals and departures. It also shows a summary of the hours of runway use by weather condition.
- **Monthly Dwell and Persistence**: The report presents the hours of dwell and persistence by noise area for each day of the month as well as the daily average dwell and persistence and goal exceedence.
- **Monthly Summary**: The summary highlights the three reports described above. It compares jet operations by runway with annual goals, shows the monthly and average day hours of runway use as well as consecutive hours of use. It also summarizes the monthly dwell and persistence conformance.
- **Monthly 33L/15R Utilization**: This report shows the number of hours between midnight and 6:00 AM during which the 33L/15R configuration was both recommended and used. It also presents the use of 33L and 15R individually during nocturnal hours.
- **Annual Utilization**: For the specified calendar year, this report presents the average and maximum consecutive hours of jet use by runway end and month. It also presents total and average annual utilization by runway and weather condition.
- **Annual Dwell and Persistence**: The final report presents the monthly dwell and persistence averages as well as annual averages and the average annual exceedence.

These seven reports are prepared by the Massport Noise Abatement Office on a monthly and annual basis. On a quarterly basis, the Massport Quarterly Noise Reports are distributed to Massport staff, FAA employees, and other requesting parties such as community

members. These reports include measured sound levels, runway use statistics, FAA traffic totals, and the late night runway use report. The quarterly report also includes a PRAS monthly summary report (a version of the summary reported by the PRAS system itself, but generated directly from the ARTS data), which includes day / night hours of jet use by runway, day / night jet operations by runway, monthly conformance relative to the annual PRAS goals, and conformance relative to the annual goals for the previous twelve months. In addition to the printed reports, both the FAA and the Massport Noise Abatement Office have real-time displays showing the rolling 12-month conformance relative to the PRAS goals as well as the current dwell and persistence counts.

In response to the EOEA Certificate and public comments, the Massport Quarterly Noise Reports will be expanded to include all of the PRAS reports generated by the system, and the distribution list will be expanded. The annual reports on runway utilization, dwell and persistence will also be included in upcoming ESPRs and annual Environmental Data Reports (EDRs). In addition, Massport and the FAA have agreed to development of a new report that will track the attainment of the PRAS recommendations.

4.3.6 Extending PRAS Overwater Nighttime Routing Preference

One potential mitigation measure proposed in the comments on the Airside Project Draft EIS / EIR is to begin the nighttime overwater routing preference before 12:00 AM or extend it beyond 6:00 AM. This would reduce late evening and early morning flights over impacted communities.

While the use of the 33L / 15R configuration is environmentally beneficial, its low capacity is a significant operational limitation. Controllers must maintain a minimum of eight miles of separation between opposite direction aircraft, limiting configuration utilization to periods of very low demand. The first step in evaluating the feasibility of extending the nighttime period is analysis of the demand profile. Table 4.3-4 presents the demand profile from 10:00 PM to 7:00 AM in 15-minute increments. Operations are distributed fairly evenly within individual hours from 10:00 PM to 12:00 AM and from 6:00 AM to 7:00 AM. The hourly demand drops from 43 operations at 10:00 PM to 22 at 11:00 PM and 13 operations at 12:00 AM. Conversely, there were only 6 average operations during the 5:00 AM hour increasing to 46 operations in the 6:00 AM to 7:00 AM period.

In order to determine the feasibility of extending the nocturnal period, the DELAYS model was used to examine an average August weekday in 1998 broken down into 15-minute increments. This analysis assumed VFR weather and calm winds, conditions under which the preferred nighttime configuration would be available. An hourly saturation capacity of 20 operations while using Runway 33L / 15R simultaneously was estimated. Figure 4.3-8 shows the average delays from various extended nocturnal periods ranging from 10:00 PM to 7:00 AM Beginning the nocturnal period before 11:00 PM or extending it past 6:15 AM would produce excessive delays. It should be noted that delays in the 6:00 AM hour could propagate throughout the day while delays in the 11:00 PM hour are quickly dissipated due to the low demand after midnight.

Table 4.3-4
Nighttime Operations (10:00 PM to 7:00 AM)

Time			Average Day Operations	
Start		End	Quarter-Hourly	Hourly
22:00	-	22:14	10.7

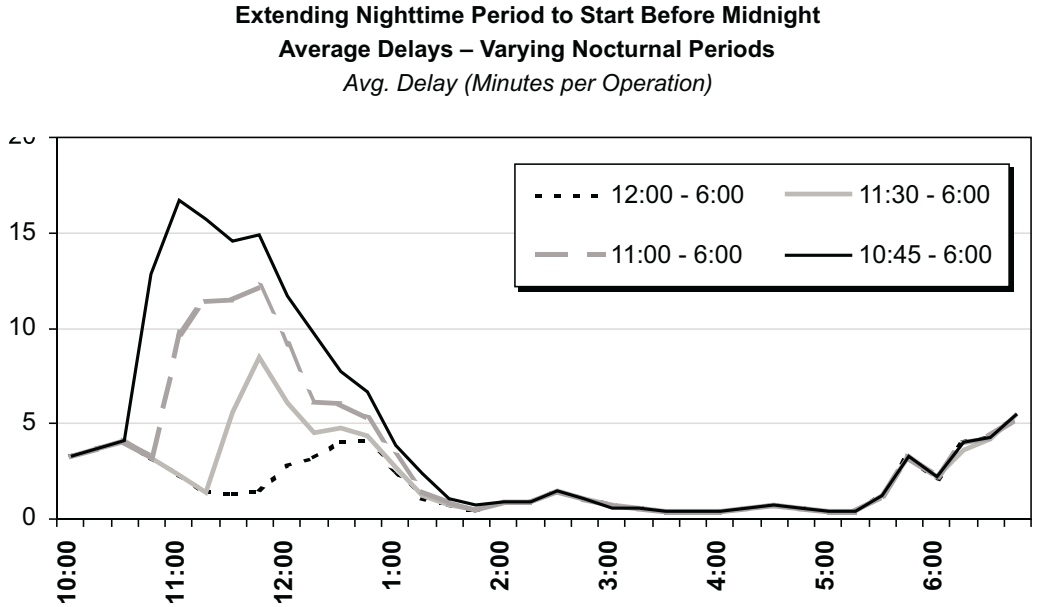
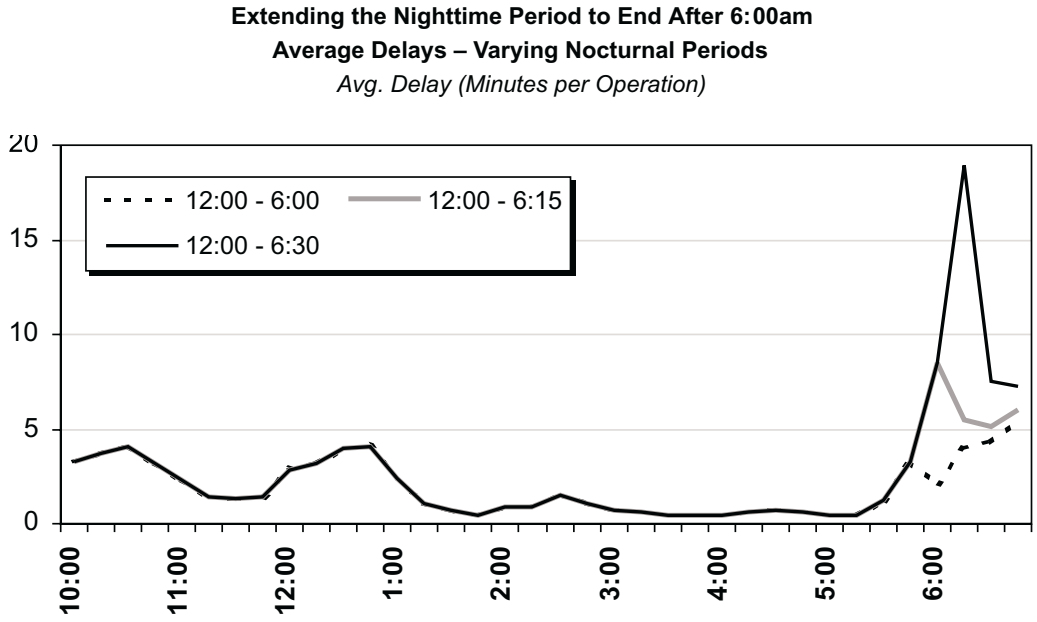
05:45	-	05:59	3.2	5.6
06:00	-	06:14	8.6	
06:15	-	06:29	12.4	
06:30	-	06:44	11.5	
06:45	-	06:59	13.5	46.0

Note: ARTS Data represents July 98 through June 99 and was processed by FTA and Massport.

Figure 4.3-8
Minutes of Average Delay by Nocturnal Period and 15-minute Increment





While the official preferential runway use policy for Logan states that the FAA will observe the nighttime priorities from 12:00 midnight to 6:00 AM, controllers currently try to switch to the Runway 33L / 15R configuration as soon after 11:00 PM as demand permits. Massport will encourage the FAA to continue this practice of initiating overwater routing preferences as soon after 11:00 PM as practicable. It is important to note, however, that controllers can only employ the 33L / 15R nighttime configuration under favorable wind and weather conditions, which limits its use to about 60 percent of the time. In addition, the extended period would only be useable if there were no delays remaining from the daytime period. Finally, it is worth noting that the takeoff and climb performance of modern Stage 3 jets is vastly improved since the nighttime priorities were established, and that departures represent a small percentage of the operations from 11:00 PM to midnight. Hence, most of the noise benefit can be achieved by using 33L for overwater arrivals, whether or not 15R can be used for departures based on the demand level.

4.4 Delay Modeling Approach

As discussed in Chapter 1, existing delay measures such as the FAA OPSNET and CODAS or the DOT ATCR have specific purposes and uses, but none provides an accurate measurement of delays caused by conditions at Logan. Most importantly, they do not provide any information on future delays, either with or without proposed airfield improvements. The only way to estimate airfield delays under alternative future scenarios is to model airfield operations under these conditions.

This section discusses the use of computer models for simulating airfield operations and delays in environmental impact analyses, and discusses the three specific models employed in the Airfield Improvements study.

4.4.1 Computer Modeling for Environmental Impact Studies

With current technology, computer models of airport operations provide the most accurate and useful estimates of airport delays for environmental planning. Computer models that simulate individual aircraft operations over a specified period of time are able to produce very detailed information on airport activity and delay statistics. Because these models calculate all aircraft movements and interactions, they are able to capture details that are not measured by published delay statistics, and they can isolate delays by cause or condition.

Table 4.4-1 summarizes the features and limitations of models available in the industry to estimate flight delays for airport planning. The table describes the three models (FLAPS, the Airport Machine, and DELAYSIM) that have been used in the Logan Airside Improvements Planning Project to estimate airfield capacities and delays, and to produce inputs to the environmental analyses. FLAPS and the Airport Machine were used to simulate runway / airspace and taxiway operations, respectively, for each Logan runway configuration. Other simulation models with similar capabilities are RDSIM, ADSIM, SIMMOD and TAAM. However, FLAPS and the Airport Machine have been specifically configured and validated for Logan operations, and both have been used for planning studies at various international airports around the world.

Table 4.4-1
Comparison on Computer Models for Airport Capacity and Delay

Model	Features	Limitations
FLAPS	Designed at MIT for Logan Detailed runway exit performance Multiple runway interactions Modest input data requirements Used at Boston, St. Louis, LaGuardia, Sydney, Amsterdam, others	Limited graphics. Excludes taxiway system.
Airport Machine	Detailed taxiway system ground movement logic. Detailed graphical presentation Used at numerous domestic and international airports	Excludes airspace system Complex data requirements
SIMMOD	FAA-sponsored development Covers taxiway, runway, airspace Used at numerous domestic & international airports	1-dimensional airspace capability Complex data requirements Inability to handle some common airport procedures
TAAM	Covers taxiway, runway, airspace High resolution 2D and 3D graphics Used at several major international airports	Very complex data requirements Requires special hardware Expensive to acquire and operate
ADSIM	Covers taxiway and runway operations Used by FAA Tech Center Used at several major US airports	Complex data requirements No aircraft landing & braking dynamics
RDSIM	Single or multiple runway operations. Used by FAA Tech Center Used at BOS and other major US airports	No graphical facilities. No aircraft landing & braking dynamics Single runway configuration
DELAYSIM*	Unique airfield utilization simulation Delays based on real weather patterns Detailed delay statistics Controller workload for runway changes Used at Boston, Amsterdam, and Sydney	Individual aircraft movements not simulated Runway selection priority required

* Indicates models used in Logan Airside Project Improvements Project

The DELAYSIM model provides a dimension of airfield modeling that is not available with any other tool. Two primary outputs of the airfield operations / delays analysis are average annual aircraft delays, which are used to measure the benefits of proposed improvements, and average annual runway utilization, which strongly influences the corresponding environmental impacts. Both runway utilization and delays are heavily influenced by the dynamic weather conditions at the airfield, which can vary significantly from year to year. To obtain delay results that account for dynamic variation yet are not biased by a specific year's weather, it is essential to analyze airfield operations under realistic weather patterns for several years and then average the results. DELAYSIM has this capability.

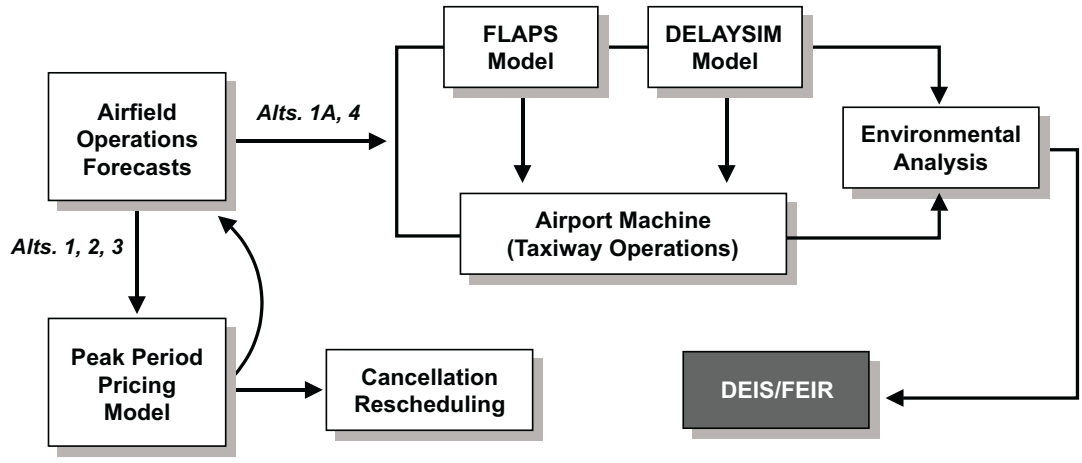
DELAYSIM is a unique model that simulates how the air traffic controllers select runways based on continuously varying demand and weather conditions. It was originally developed specifically for Logan during the enhanced PRAS project, and augmented by incorporating the MIT DELAYS model to estimate the aircraft delays. DELAYS is a dynamic queuing model for estimating expected delay, queue length and other statistics. DELAYSIM simulates the controllers' runway selection process hour-by-hour using historical weather observations. This procedure is repeated for each hour in a multi-year sequence of weather observations, and the results are averaged to produce the expected utilization and delays. The use of multi-year weather observations was particularly beneficial at Boston, where weather conditions can vary widely from year to year.

4.4.2 Airside Modeling Methodology

The airside delay modeling approach was specifically designed to measure historic and future aircraft operating delays by simulating operating conditions at Logan, and to estimate the reduction in delay that each of the proposed alternatives would produce. The models simulate the actual movement of individual aircraft from the approach fix to arrival runway to the gate for arriving aircraft, and from the gate to take-off runway to the departure fix for departing aircraft. Modeling at this high level of detail enables the delay model to generate inputs for the noise and air quality models, ensuring consistency between the estimates of future delays and environmental impacts.

Figure 4.4-1 provides an overview of the modeling approach used to calculate changes in delay and shows how the delay modeling components are linked to the models used to simulate taxiway operations and estimate environmental impacts. This diagram outlines the basic building blocks of the integrated modeling system and indicates the interactions between model components. The operational modeling methodology was described in detail in Chapter 4 of the Airside Project Draft EIS/EIR.

Figure 4.4-1
Delay Modeling Approach



4.5 Peak Period Pricing

Peak Period Pricing is intended to reduce delays caused when demand for airfield access exceeds airfield capacity over a sustained period as a result of airline overscheduling. It is an administrative option that raises the price of using the airfield during these defined peak periods. By raising the price of airfield access during peak periods, some existing aircraft operations would be discontinued or shifted to non-peak hours because the value derived from using Logan during these periods is exceeded by the new cost of doing so.

The methodology used to model and evaluate the impacts of Peak Period Pricing was fully described in the Airside Project Draft EIS/EIR. This section describes supplementary analyses performed for the Supplemental DEIS/FEIR. It includes an assessment of an illustrative exemption program designed to mitigate potential service disruptions at small communities. In addition, the discussion of Peak Period Pricing is expanded to consider potential impacts of the program on regional carrier fleet mix, and the possibility that Peak Period Pricing would result in increased regional airline reliance on alternate regional airports to provide connections from small communities to the national air transportation system.

While Peak Period Pricing is not included for immediate implementation, the delay analysis described later in this chapter indicates that this demand management strategy could represent a viable delay reduction measure under potential future conditions of airline overscheduling. In response to the EOEA Certificate, this section includes a description of a Peak Period Monitoring System that will be established by Massport to determine when and if airline overscheduling is emerging as a significant source of Logan delays. When warranted based on this ongoing schedule monitoring system, Massport will begin collaborative discussions with individual carriers in order to encourage increased scheduling efficiency at Logan. If successful, this initiative will reduce the likelihood that airline overscheduling will develop at Logan such that a Peak Period Pricing program would become necessary. If these discussions do not produce the necessary results, appropriate regulatory action will then be undertaken.

4.5.1 Background

Alternatives 1, 2 and 3 include Peak Period Pricing, which is defined in detail in Section 3.5. Peak Period Pricing differs from the other proposed improvements because it reduces delay by eliminating flights during periods of high demand, rather than by improving the airfield to allow for more efficient accommodation of existing flight demand.

The analysis of Peak Period Pricing was based on the introduction of a $150 surcharge on flights arriving or departing Logan Airport during defined peak periods. The impacts of the program were most pronounced for regional carriers operating small aircraft in the 9- and 19-seat classes, because the fixed surcharge resulted in a significant cost increase on a per passenger basis. The implementation of Peak Period Pricing was forecast to produce flight cancellations in nonstop markets where profitability was substantially reduced.

Because many of New England's small- and medium-sized communities rely heavily on Logan for access to the national air transportation system, reductions in Boston service could have adverse economic consequences. These issues were addressed in Appendices F and G of the Airside Project Draft EIS/EIR which present case studies concerning the impact of Peak Period Pricing on selected Logan regional carriers and small communities. It is in response to concerns regarding market access that the illustrative small community exemption program is addressed in this Supplemental DEIS/EIR.

The delay reduction benefits that result from Peak Period Pricing were described in Chapter 4 of the Airside Project Draft EIS/EIR. The projected delay reduction impacts of Peak Period Pricing are based on forecast changes in flight schedules in response to the modified landing fee structure. The reductions in forecast annual Logan aircraft operations attributed to Peak Period Pricing are summarized below in Table 4.5-1 for the 29M Low Fleet and 37.5M High Fleet scenarios.

On an annual basis, Peak Period Pricing is estimated to reduce aircraft traffic at Logan by 4,000 annual operations under the 29M Low Fleet scenario and by 56,000 operations under the 37.5M High Fleet scenario. The table also illustrates the reduced level of annual aircraft operations for those Alternatives that include Peak Period Pricing as an improvement concept.

The cancellation rate associated with the High Fleet scenario is considerably greater than for the Low Fleet scenario, because the designated peak periods of the High Fleet scenario are longer, thereby producing a greater cost increase. The regional industry is also more competitive and less profitable under forecast High Fleet conditions. Therefore regional carriers would have less flexibility to absorb cost increases before deciding to cancel flights.

Table 4.5-1
Estimated Annual Peak Period Flight Cancellations and Impact on Fleet Assumptions

Forecast Scenario	Forecast Logan Operations (Alternatives 1A and 4)	Estimated Annual Cancellations	Forecast Logan Operations (Alternatives 1, 2 and 3)
29M Low	510,000	4,000	506,000
37.5M High	608,000	56,000	552,000

4.5.2 Potential for Changes in Regional Carrier Fleet Mix in Response to Peak Period Pricing

In responses to the EOEA Certificate, this section describes the potential effect of Peak Period Pricing on changes in aircraft fleet mix.

By applying a fixed surcharge to flights operating in designated peak periods, the tested pricing structure provides a competitive advantage to carriers operating larger aircraft and carrying a greater number of onboard passengers. This is because the fixed peak period fee can be spread over a greater number of passengers, producing a lesser impact per

passenger. The fixed surcharge would therefore accentuate the unit cost advantage already exhibited by larger capacity regional carrier aircraft over smaller equipment.

In the analytic framework used to evaluate the impacts of Peak Period Pricing on market services and Logan delays, carriers were assumed to shift flights scheduled near the beginning and end of the defined peak period to adjacent, off-peak hours in order to avoid the peak period surcharges. On nonstop routes where a regional carrier was projected to incur a significant reduction in profitability due to the cost impacts of the program, cancellation of some peak period flights was projected. The percent of peak period flights cancelled in specific carrier markets was directly related to the degree of profit reduction. Carriers operating smaller regional aircraft in the 9- and 19-seat class were projected to account for the majority of flight cancellations.

In markets where Peak Period Pricing leads to a reduction in flight frequency during peak hours, carriers may be able to consolidate passenger traffic on remaining peak period flights. In some cases, a carrier that had the option within its fleet might substitute a larger capacity aircraft on remaining flights to better accommodate the passenger traffic previously carried on cancelled flights.

Over a near-term horizon, the opportunities for regional carriers to substitute larger aircraft on Logan routes would be limited by their aircraft fleet composition. Many of the regional airlines operating at Boston maintain an aircraft fleet consisting of a single type of aircraft. For example, Cape Air operates only 9-seat Cessna aircraft, while Commutair and Colgan operate 19-seat Beech 1900 aircraft exclusively. Similarly, Allegheny operates only 37-seat Dash 8-100 aircraft.[5] Business Express, recently acquired by American Airlines, has already phased out its 19-seat aircraft, while American Eagle operates only aircraft with greater than 30 seats.

Several Logan regional carriers maintain fleets consisting of multiple aircraft types in varying size categories. It is reasonable to expect that Peak Period Pricing would lead to aircraft substitutions on specific routes served by these carriers in circumstances where the use of larger aircraft would improve market profitability. These types of fleet mix changes were anticipated in the analysis developed in the Airside Project Draft EIS/EIR and are consistent with the results. Fleet mix changes were not explicitly projected because of the uncertainty of these changes and because the delay modeling analysis is more sensitive to changes in flight frequency as compared to changes in aircraft size within the regional non-jet fleet.

The EOEA Certificate and several comments also raised the prospect of regional carriers shifting flights from Logan to alternate airports in the region. Two classes of passengers currently fly on regional carrier flights to and from Logan:

- Local passengers for whom Boston or the surrounding region is the origin or destination of their trip
- Passengers connecting at Boston to or from other domestic or international destinations.

5 Source: 1999 Regional Airline Association Annual Report.

For local passengers, particularly those with ground origins or destinations in the immediate Boston area, the use of other airports in the region may not represent a viable alternative. Because Boston is the largest city in the region, it generates the highest concentration of passenger demand to and from regional carrier markets. The use of alternate airports such as Manchester, Providence or Worcester would be accompanied by a significant reduction in local passenger traffic.

For passengers making connections at Boston to and from the national air transportation system, the regional airports would also represent a less desirable alternative. Even with the recent expansion of services at regional airports such as Providence and Manchester, the frequency and diversity of potential connecting services at these airports fall well below the services available at Boston. Shifting flights now serving Boston to one of the alternate regional airports would again be expected to produce a reduction in connecting passenger demand.

For these reasons, the analysis presented in the Airside Project Draft EIS/EIR does not assume that regional carriers would respond to Peak Period Pricing by shifting Boston flights to alternate airports. While some limited flight shifts to alternate airports could occur, it is not expected that a substantial portion of Logan's existing regional carrier services could be economically supported at alternate regional airports.

4.5.3 Analysis of Peak Period Pricing Exemption Program

The effects of Peak Period Pricing on access to Logan were examined in the regional carrier and small community case studies presented in Airside Project Draft EIS/EIR. This issue was the subject of numerous comments voiced at public hearings and received in formal comment letters addressing the Airside Project Draft EIS/EIR. Comments were received from residents and public officials representing potentially affected communities, and from other interested parties. The EOEA Certificate specifically requested that Massport explore the issue of a tightly crafted exemption program designed to mitigate potential service disruption at small communities.

In response to these concerns, this section expands the Peak Period Pricing analysis presented in the Airside Project Draft EIS/EIR to reflect the inclusion of an exemption program. The purpose of the expanded analysis is to determine whether a limited exemption program could successfully mitigate some of the negative service related impacts of Peak Period Pricing without unduly diluting the effectiveness of Peak Period Pricing as a vehicle to reduce airline overscheduling and its associated delays.

Parameters and methodology used in evaluating the illustrative exemption program are described below:

- Communities were considered as eligible for Peak Period Pricing exemptions if they qualified for the Federal Essential Air Service (EAS) program, and if Boston was designated as a qualifying hub destination. Based on this criterion, 16 New England communities (Figure 4.5-1) were included in the illustrative exemption program. Provincetown, MA was added to the exemption program, despite its lack of EAS

eligibility, because previous analysis indicated that this market relied exclusively on Boston for access to the national airport system, and consequently would potentially bear a unique, disproportionate burden resulting from Peak Period Pricing at Logan. Burlington, VT was not included because it has EAS to New York.

- A total of two daily roundtrips (or four operations) during the peak period were exempted from peak period surcharges at each of the exemption markets. This is consistent with the Federal EAS program that guarantees small communities a minimum of two daily roundtrips to a designated hub airport and will provide subsidy when necessary to maintain this level of essential air service. In markets served by multiple carriers, exemptions were allocated between carriers based on the level of peak period flights each carrier provided to Boston.

- Reflecting the reduction in peak period surcharges, the weight-based landing fee was adjusted to retain an approximately constant level of total airfield revenue, consistent with current federal guidelines.

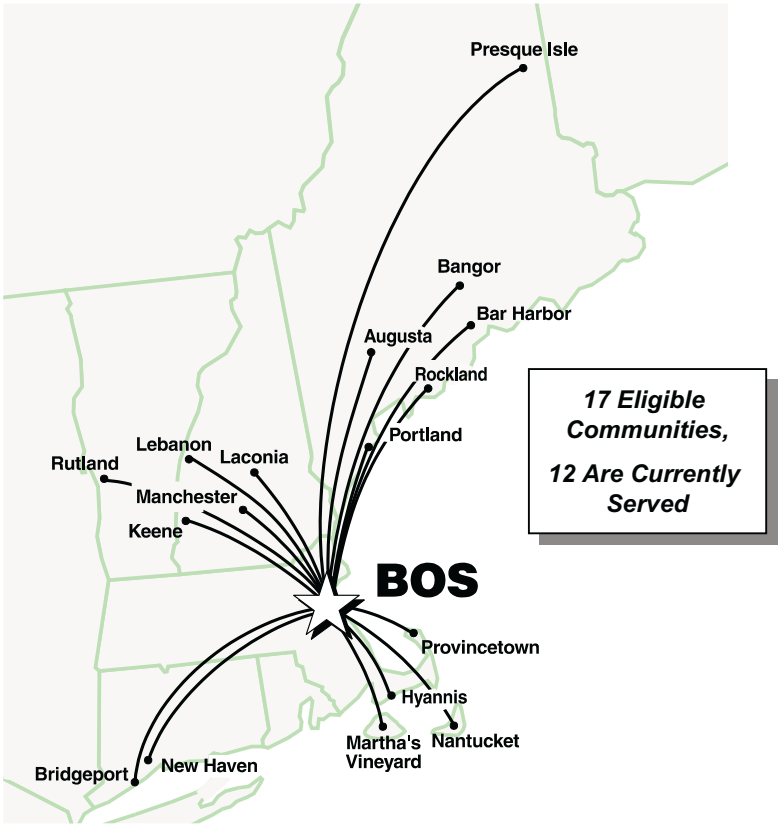
- Cost impacts of the modified Peak Period Pricing program were evaluated by carrier and nonstop market using the schedule patterns and modeling framework previously applied for three future fleet scenarios: the 29M Low Fleet and the 37.5M Low and High Fleets. The 29M Low Fleet approximates current operating conditions at Logan, while the 37.5M Low and High Fleets bound the range of likely future activity levels at the airport.

- Flight shifts and cancellations were projected under each scenario using the methodology and assumptions as described previously in this chapter.

- The daily demand profiles were adjusted to reflect the projected shifts and cancellations of peak period flights. The adjusted profiles were then evaluated using the DELAYSIM model to determine the delay reduction impacts of a Peak Period Pricing program as modified to reflect an illustrative small community exemption program.

In addition to the illustrative exemption program elements described above, consideration will also be given to operational factors, such as the use of the 2,557 foot Runway 15L/33R, that may justify exemptions without jeopardizing the delay reduction benefits of Peak Period Pricing. If appropriate, these operational factors would also be incorporated as part of any Peak Period Pricing exemption program that may be implemented in the future.

Figure 4.5-1
Communities Eligible for Exemptions



4.5.3.1 Results of Exemption Analysis

The exemption from peak period surcharges of two daily roundtrips from eligible communities reduces the initial cost impacts of the program on the regional carriers that serve these markets. This lower cost impact translates to lower required fare increases and, ultimately, tempers the profit margin reduction incurred by carriers serving these routes. As a result, the predicted level of flight cancellations with an exemption program is correspondingly less than the projections previously developed for Peak Period Pricing without exemptions.

Table 4.5-2 shows the comparative percent of flights cancelled, with and without the exemption program, from eligible communities. As illustrated in the table, the cancellation percentages are universally lower with the illustrative exemption program. Under the 29M Low Fleet scenario, only 1.3 percent of summer season flights from exemption eligible communities are projected to be cancelled. This compares to a 4.4 percent cancellation rate projected at these communities prior to exemptions. Under the 37.5M Low Fleet, the cancellation rate falls from an original 5.8 percent down to 1.7 percent with exemptions. Under the 37.5M High Fleet scenario, the projected cancellation rate falls to 15.8 percent with exemptions from 22.6 percent in the original analysis.

Table 4.5-2
Comparison of Projected Service Impacts With and Without Peak Period Exemptions

	Projected Flight Cancellations as Percent of Total Daily Operations					
	Without Exemptions			With Exemptions		
Airport	29M Low	37.5M Low	37.5M High	29M Low	37.5M Low	37.5M High

Bridgeport	0.0%	0.0%	0.0%	0.0%	0.0%	0.0%
Total	**4.4%**	**5.8%**	**22.6%**	**1.3%**	**1.7%**	**15.8%**

Note: "-" indicates the EAS airport had no service to Boston in the corresponding scenario.

The 37.5M High Fleet scenario exhibits the smallest decline in projected service impacts due to the illustrative exemption program. This is because the designated peak period under this scenario extends from 7:00 AM to 8:59 PM (i.e., a span of 14 hours). As a result, the two daily roundtrips that were exempted from peak period surcharges represent a proportionately smaller benefit than realized under the alternative Low Fleet scenarios, with their shorter peak periods (5 to 6 hours). Because a significant proportion of peak period flights under the 37.5M High Fleet scenario would continue to be assessed surcharges, the cost mitigation effects of the exemption program are less pronounced and produce a smaller impact on projected flight cancellations.

4.5.3.2 Delay Reduction Impacts

By reducing the number of projected flight cancellations at eligible communities, the exemption program allows more flights to operate during peak periods and lowers the projected delay reduction benefits of Peak Period Pricing (see Table 4.5-3).

Under the 29M Low Fleet scenario, inclusion of the small community exemption program reduces the projected delay reduction benefits of Peak Period Pricing (and Reduced Minimums) by approximately 2,700 hours, with Alternative 2 producing a 6.2 percent

reduction in annual runway-related delays (vs. Alternative 4) as compared to an 8.1 percent reduction without exemptions.

In the 37.5M Low Fleet, the exemption program reduces the delay reduction impact of Peak Period Pricing by 8,100 annual hours. With exemptions, Alternative 2 (which include Peak Period Pricing and Reduced Minimums) reduce annual runway delays by 7.7 percent compared to an 11.1 percent reduction prior to exemptions.

Table 4.5-3
Exemption Program: Delay Reduction Impacts

	Annual Hours of Runway Delay		
Alternative	**29M Low**	**37.5M Low**	**37.5M High**
Alternative 4 – No Action	136,400	233,900	332,700
Alternative 2 – Administrative Actions Only – No Exemptions	125,300	207,900	194,000
Alternative 2 – Administrative Actions Only – With Exemptions	128,000	216,000	208,900
Delay Reduction			
Alternative 4 vs. Alternative 2 – No Exemptions	**11,100**	**26,000**	**138,700**
Alternative 4 vs. Alternative 2 – With Exemptions	**8,400**	**17,900**	**123,800**

Under the 37.5M High Fleet conditions, the exemption program lowers forecast delay savings by approximately 15,000 annual hours. Under this scenario, Alternatives 2 and 3 would produce an estimated 37.2 percent reduction in delay with the exemption program, as compared to a 41.7 percent reduction in runway delays prior to exemptions.

4.5.3.3 Findings of Exemption Program Analysis

The inclusion of a small community exemption program reflects the trade-off between the potential delay reduction benefits of Peak Period Pricing and recognition of the importance of preserving access to Logan from small and medium-sized New England communities. The illustrative exemption program described above was patterned after the Federal Essential Air Service (EAS) Program. Eligible communities were those markets with EAS determinations that designated Boston as a qualifying hub destination. The number of exemptions was established at two daily roundtrips, also consistent with the EAS standard.

By granting a limited number of exemptions to eligible cities, the projected service disruption caused by Peak Period Pricing would be reduced. In limiting the number of exemptions to two daily roundtrips during peak periods, the effectiveness of Peak Period Pricing in reducing delays is generally maintained, particularly under the 37.5M High Fleet scenario where Peak Period Pricing was recommended as an appropriate delay reduction strategy.

4.5.4 Peak Period Monitoring System

Peak period pricing was evaluated as a demand management program designed to limit airline overscheduling at Logan. Overscheduling was a problem in 1993 when airline flight schedules during peak periods exceeded Logan's available capacity. Since 1993, the hourly flight profile at Logan has flattened and current peak period demand can be accommodated with minimal delay during normal operating conditions. Because airline overscheduling is not a significant source of current delays at Logan, Massport did not recommend Peak Period Pricing for immediate implementation in the Preferred Alternative.

However, the analysis in the Airside Project Draft EIS/EIR indicates that under some future scenarios, overscheduling could re-emerge as a significant source of delays, and Peak Period Pricing could produce substantial delay reduction benefits. Based on this finding, Massport stated in the Airside Project Draft EIS/EIR that it would reserve the option to implement Peak Period Pricing, should this be warranted by future flight activity patterns at Logan.

The EOEA Certificate requires that Massport define the conditions that would lead to the implementation of a Peak Period Pricing program. In response, Massport will establish a monitoring system to provide advance warning of when overscheduling is likely to become a significant contributor to delays at Logan. If so, the system would identify the portion of the day where an overscheduling condition would likely occur. This information would then be used as a basis for initiating a discussion with the carriers on how to achieve timely corrective action. If the necessary corrective action is not agreed to then appropriate regulatory action would be taken to reduce or eliminate overscheduling as a source of airfield delays at Logan.

While the detailed structure of the proposed monitoring system has not been finalized, key components of an illustrative monitoring system are described below:

- Projections of Logan flight activity will be developed on a semi-annual basis. These projections will be prepared 4 to 6 months in advance and will represent estimates of flight levels by hour for the upcoming season. Projections will be based on the most recent activity levels at Logan, historic seasonality patterns, and on advance flight schedules submitted by carriers to the OAG, expanded to reflect non-scheduled activity including charter and general aviation. Advance carrier flight schedules have been a reliable indicator of future activity at Logan, as illustrated in Table 4.5-4.

- Logan's average capacity under VFR weather conditions will be evaluated as required to account for fleet mix changes and advances in air traffic control technology as required. VFR conditions are available approximately 80 percent of the year.

- Delays due to overscheduling will be quantified through an analysis that simulates the projected flight schedule against Logan's average VFR capacity. Delays will be estimated by hour to permit designation of a specific peak period when overscheduling conditions are causing significant delays.

- A phased Peak Period Pricing curative process would be initiated when projected delays due to airline overscheduling reach or exceed an average level of 15 minutes per flight over a period of three or more consecutive hours. The 15-minute criterion is based on the FAA threshold for identifying significant delay.

Table 4.5-4
Comparison of Advanced and Actual Flight Schedules for Logan

Year	Daily Nonstop Logan Departures for August		Percent Difference
	Advanced	Actual	
1998	707	724	2.4%
1999	691	689	-0.2%

Note: Advanced schedules based on April OAG Schedule Tape.
Source: Official Airline Guide, Schedule Tapes.

Phase 1: Voluntary Schedule Adjustments

When the 15-minute delay threshold is projected to be exceeded, Massport will first meet individually with airlines that exhibit significant levels of flight activity during the identified peak period. These carriers would be informed that Peak Period Pricing will be invoked unless flight schedules are reduced below threshold levels. If voluntary schedule adjustments occur, the Peak Period Pricing regulatory requirements would be deferred.

Phase 2: Regulatory Action

If voluntary schedule adjustments do not eliminate the overscheduling situation, Massport will take the necessary steps to implement Peak Period Pricing at Logan. Massport will continue to monitor flight schedules and make adjustments to the peak period as warranted by future schedule changes. Massport will also make other adjustments to the monitoring system and the Peak Period Pricing program if necessary to effectively address any overscheduling situation that may arise.

4.6 Aircraft Delay and Runway Use Results

The Logan airfield modeling methodology, described in Chapter 4 of the Airside Project Draft EIS/EIR, was used to estimate aircraft delays and runway utilization for the 1993 historic analysis and for each of the future passenger demand and aircraft activity levels. To provide perspective on current conditions at Logan, additional analysis of 1998 conditions was also performed for this Supplemental DEIS/FEIR. At the request of the SDEIS Panel, a new 37.5 million passenger High Regional Jet Fleet (37.5M High RJ Fleet) scenario was also examined; the results of the High RJ Fleet analyses are presented in Section 4.7.

4.6.1 Analysis of Historic (1993) and Current (1998) Delays

The year 1993 represents a peak year for small aircraft operations at Logan Airport. Flight operations in 1993 also exhibited a relatively high degree of hourly peaking compared to the current, flatter operations profile at Logan. The year 1993 was originally chosen as an analysis year since it represented the most recent complete year of available data at the beginning of the Logan Airside Improvements Feasibility Study. Though considerable time has passed since 1993, the analysis year illustrates operating and environmental conditions at Logan during a period of airline overscheduling and high delays.

To supplement the 1993 historic analysis, 1998 conditions have been studied in the Supplemental Draft EIS/Final EIR to provide a more recent point of reference. Since 1998 has less hourly peaking, delays are lower than those in 1993, even though total demand was nearly the same. While these years provide context for historic and current conditions at Logan, the appropriate data for assessing the benefits of the proposed Airside Project improvement concept in future years is a comparison of the action Alternatives (Alternatives 1, 1A, 2 and 3) to Alternative 4, the No Action Alternative. The 1993 and 1998 analyses are useful for model calibration and for providing a frame of reference.

The 1993 historic analysis estimated 159,000 annual hours of aircraft delay at Logan, with 135,000 hours of delay related to runway congestion and 24,000 hours resulting from taxiway congestion. The delay analysis for 1998 indicates that Logan incurred 120,000 hours of runway-related delays in that year, comparable but slightly below the 1993 level of 135,000 hours. While detailed simulation of taxiway movements were not conducted for 1998, an estimated 22,000 annual hours of taxiway delays occurred in 1998 based on interpolation from other modeled scenarios. Incorporating both runway and taxiway delays for 1998, Logan experienced total aircraft delays of approximately 142,000 hours during the year.

Analysis of 1998 Delays with the Preferred Alternative

In addition to modeling actual Logan operating conditions and delays, the analysis also re-modeled 1998 activity assuming that the airfield improvements contained in the Preferred Alternative were in place. This analysis quantifies the delay reduction benefits that would have been realized at Logan in 1998 if the Preferred Alternative had been implemented.

Logan operations during 1998 were analyzed using 1998 runway utilization from the *1998 Annual Update* and actual 1998 weather observations. The version of DELAYSIM used for the 1998 delay analysis included an added feature for tabulating delays by wind direction. In order to demonstrate the benefits of Runway 14/32 under northwest wind conditions, the analysis of actual 1998 conditions was compared to projected 1998 results assuming that the Preferred Alternative improvements were in place.

Similar to the results for future year operating conditions, if Runway 14/32 had been available in 1998, Logan would have experienced a 32 percent reduction in runway delays, or 82,000 hours versus 120,000 hours without the Preferred Alternative improvements (Table 4.6-3). While this improvement is significant, the analysis of VFR delays is even more compelling and demonstrates the impact of unidirectional Runway 14/32 on VFR delays, particularly under northwest wind conditions. Figure 4.6-1 shows that the Preferred Alternative would have reduced 1998 VFR delays by 69 percent, from 51,000 annual delay hours to only 16,000 hours.

Figure 4.6-1 also categorizes 1998 VFR delays by wind direction. As shown in the figure, delays from northwest winds made up 70 percent of VFR delays in 1998. Since winds from the northwest accounted for only 37 percent of the 1998 VFR weather conditions, northwest winds generated a disproportionate percentage of the VFR delays. The disproportionate share of VFR delays that occur during northwest winds demonstrates the inefficiency caused by Logan's lack of a third runway in the northwest-southeast orientation. A comparison of the 1998 No Action and Preferred Alternative results indicates that Runway 14/32 would have had a dramatic effect on VFR northwest wind delays in 1998, reducing them by nearly 90 percent. This case study of VFR delays under northwest wind conditions demonstrates the effectiveness of Runway 14/32 under current operating conditions at Logan.

4.6.2 Total Delays

Massport selected Alternative 1A as its Preferred Alternative (all actions except Peak Period Pricing) because airline overscheduling is not currently a problem at Logan. Further, the delay reduction benefits associated with Peak Period Pricing come at a cost to passengers, communities and the regional carriers. If airline overscheduling emerges as a significant contributor to Logan delays, the monitoring program provides for a clear plan of action to alleviate that condition (see Section 4.5.4).

The following discussion analyzes the delay reduction savings associated with the Preferred Alternative under two fleets that reflect a broad range of likely operating conditions at Logan over the near and long term—the 29M Low Fleet and the 37.5M High Fleet.

Figure 4.6-1
Annual VFR Delay Hours by Wind Direction

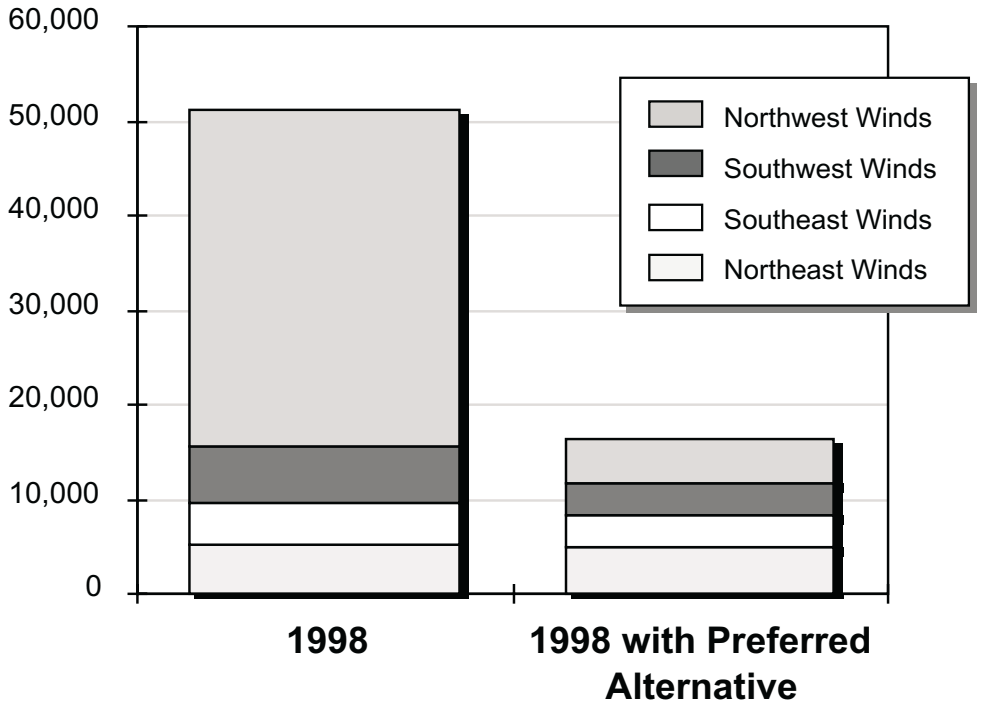

Table 4.6-1 compares the results of the operating delay analysis of the Preferred Alternative versus the No Action Alternative under the 29M Low Fleet and the 37.5M High Fleet scenarios. The airfield operations analysis indicates that Logan will incur extremely high levels of delay if no actions are taken to improve airport operating efficiency. For the No Action Alternative (Alternative 4) under the 29M Low Fleet, which reflects the lowest growth in aircraft operations, Logan passengers and airlines are forecast to experience 157,500 annual hours of delay. Even under this most conservative growth scenario, the extent of Logan's delay problem is highlighted by the FAA's threshold of 20,000 annual hours of delay which is used to identify severely congested (i.e., delay prone) airports. If aircraft operations at Logan reach the level projected under the 37.5M High Fleet, delays could exceed 360,000 hours per year, more than double the 159,000 hours of modeled delay in the 1993 historic analysis.

Under Low Fleet conditions that are most similar to current conditions at Logan (29M Low), the Preferred Alternative produces a delay reduction contribution of over 43,000 hours. This represents a savings in delay of approximately 27 percent under likely near term conditions as shown in Table 4.6-2.

Table 4.6-1
Total Hours of Runway and Taxiway Delay by Alternative and Fleet Scenario

Alternative	Runway and Taxiway Total Annual Delay Hours	
	29M Low	37.5M High
Total Delay		
Preferred Alternative - All except Peak Period Pricing	114,450	249,600
Alternative 4 - No Action	157,500	363,400
Delay Reduction		
Alternative 1 vs. Alternative 4	46,100	194,800
Preferred Alternative vs. Alternative 4	43,050	113,800

Table 4.6-2
Percent Reduction in Total Annual Hours of Delay by Fleet Scenario for the Preferred Alternative (Including Runway and Taxiway Delay)

Improvement Concept	Percent Delay Reduction vs. No Action	
	29M Low	37.5M High
Preferred Alternative - All except Peak Period Pricing	-27.3%	-31.3%
	Annual Hours of Delay	
Alternative 4 – No Action	157,500	363,400
Preferred Alternative	100,000	200,000

The contribution of the Preferred Alternative grows rapidly in future conditions. The 37.5 M High Fleet represents an appropriate upper bound for future conditions at Logan. Under this future High Fleet scenario, the Preferred Alternative produces 114,000 hours of delay reduction—a savings that is comparable to the current level of runway related delay at Logan. The Preferred Alternative would provide delay savings of 31.3 percent compared to the No Action Alternative.

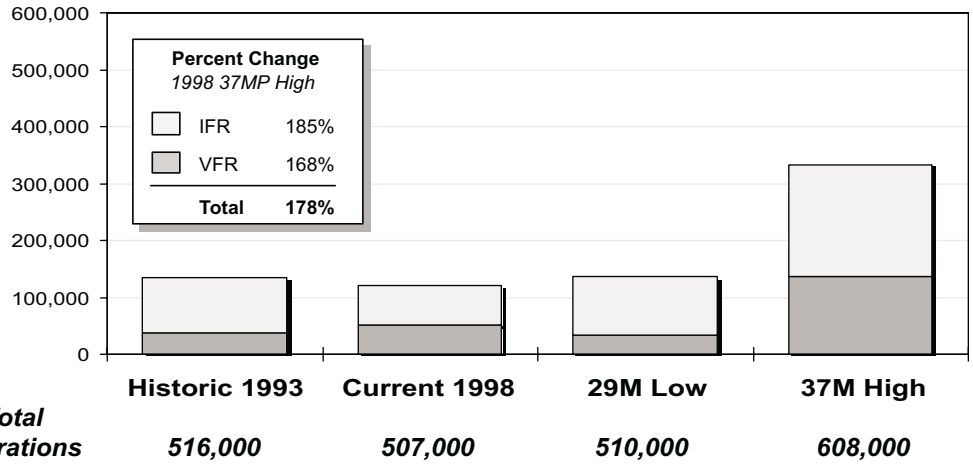
In the 37.5M High Fleet scenario, flights at Logan would experience an average delay of 36 minutes per flight (runway plus taxiway delay). Based on the estimated $2,500 per hour cost of aircraft delay, including both aircraft operating expenses and the value of time for airline passengers, the potential level of delays in the 37.5M High scenario could cost airlines and passengers $925 million if no improvements are made.

4.6.3 Runway Related Delays

Total Logan operating delays can be segmented into two principal components—runway delays and taxiway delays. Separate analysis of these segments provides a clearer understanding of the benefits associated with the Preferred Alternative. Runway-related delays account for the majority of aircraft delays at Logan. The Preferred Alternative will significantly reduce runway-related delays, but because of limited runway capacity under severe weather conditions, Logan will continue to experience some runway-related delay under all forecast scenarios.

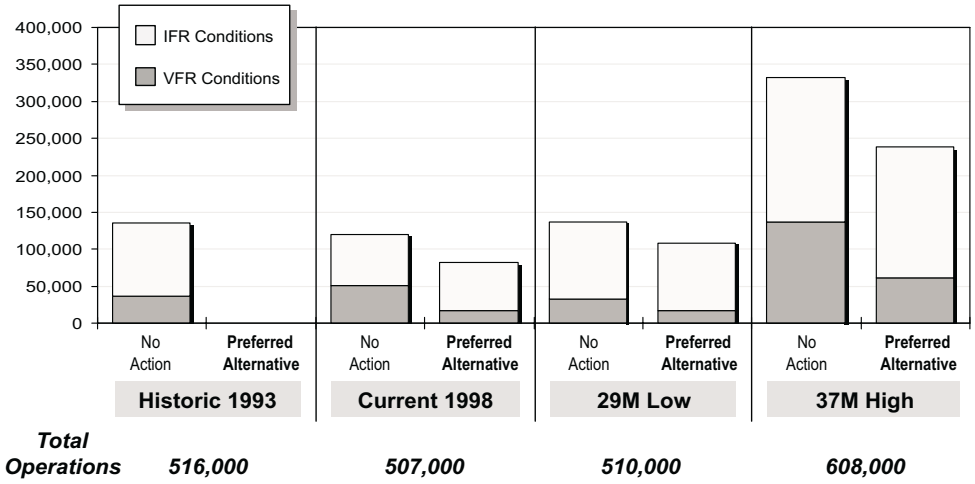
Figure 4.6-2 shows the forecast distribution of runway delays between VFR (Visual Flight Rules) and IFR (Instrument Flight Rules) weather conditions at Logan. IFR conditions reflect poor weather that ranges from low cloud cover to heavy fog and blizzards. While IFR conditions prevail less than 15 percent of the time at Logan (using the ten-year weather data), a disproportionately high share of historic airport delays have occurred during these conditions. In 1993, for example, over 70 percent of modeled delays occurred in IFR conditions. In 1998, (with actual 1998 weather), IFR conditions occurred 13 percent of the time and made up 57 percent of the delays.

Figure 4.6-2
Forecast Annual Hours of Delay by Weather Condition – No Action Alternative



As shown in Figure 4.6-3, future growth in aircraft operations will produce large increases in VFR delays under the No Action Alternative. Under the 37.5M High Fleet scenario, VFR delays will increase by 168 percent over 1998 levels if no actions are taken to address the delay problem at Logan. Conversely, implementation of the Preferred Alternative (Alternative 1A) will substantially reduce the growth in delays occurring in VFR conditions. Under the 37.5M High Fleet scenario, if the Preferred Alternative is implemented VFR delays would be reduced by over 50 percent compared to the No Action Alternative.

Figure 4.6-3
Forecast Annual Hours of Delay by Weather Condition – Preferred Alternative vs. No Action Alternative



As Table 4.6-3 shows, if no action is taken, runway delay could grow from 120,000 hours in 1998, to 333,000 hours under 37.5M High Fleet conditions. This represents an increase of 175 percent. The Preferred Alternative would reduce runway-related delays by 38,000 hours under current conditions and 94,000 hours in the 37.5M High Fleet scenario.

Table 4.6-3
Hours of Delay by Alternative and Fleet Scenario

	Runway Related Delay		
Alternative	**1998**	**29M Low**	**37.5M High**
Preferred Alternative - All except Peak Period Pricing	82,000	108,000	239,000
Alternative 4 - No Action	120,000	136,000	333,000
	Delay Reduction		
Preferred Alternative vs. Alternative 4	**38,000**	**28,000**	**94,000**

4.6.4 Taxiway Related Delays

The second component of airfield delay at Logan is taxiway delay. While the level of taxiway delays at Logan is not as high as delays associated with runway constraints, the airfield operations analysis indicates that taxiway improvements will provide substantial delay reduction. Table 4.6-4 shows the level of taxiway-related delays associated with the Preferred Alternative in comparison to the No Action Alternative.

The taxiway delay reduction associated with the Preferred Alternative ranges from 15,000 annual hours under the 29M Low scenario to 19,800 hours under the 37.5M High Fleet scenario. At approximately $2,500 per hour of delay, the potential reduction in taxiway-related delays represents annual cost savings of between $37 and $49 million.

Table 4.6-4
Hours of Taxiway Delay by Alternative and Fleet Scenario

	Taxiway Related Delay	
Alternative	**29M Low**	**37.5M High**
Preferred Alternative – All except Peak Period Pricing	6,450	10,600
Alternative 4 – No Action	21,500	30,400
	Delay Reduction	
Preferred Alternative vs. Alternative 4	**15,050**	**19,800**

Taxiway construction improvements make the largest contribution to reduction in taxiway delays, but the addition of unidirectional Runway 14/32 also contributes to taxiway delay savings. The availability of Runway 14/32 permits a shift in runway usage patterns that allow the use of more efficient taxiway configurations. Under the 37.5M High scenario, Alternative 2 which includes taxiway construction (but does not include Runway 14/32) reduced delay by 4,900 hours per year compared to Alternative 3 which does not include taxiway improvements. The construction of Runway 14/32, included in the Preferred Alternative, reduces taxiway-related delay by a further 4,700 hours per year in addition to reducing runway-related delays. Appendix K of the Airside Project Draft EIS/EIR includes the "Taxiway Delays Case Study" which examined taxiway delays during periods of peak terminal utilization.

4.6.5 Runway Use

The delay reduction benefits associated with Alternative 1A were critical to its selection as the Preferred Alternative. A second important factor was the effect that Runway 14/32 would have on runway use patterns which in turn directly impacts both the level and distribution of aircraft related noise. The addition of Runway 14/32 and the resultant flexibility that controllers would have to shift runway use patterns provides the communities to the north and south of Logan substantial relief from noise, while at the same time moving a substantial portion of Logan's operations over water. By reducing the reliance on north/south runways, Runway 14/32 allows greater performance relative to the PRAS annual runway use goals—in fact, the predicted PRAS conformance nearly doubles with Runway 14/32. Without unidirectional Runway14/32, the communities to the north and south of Logan will bear an increasingly disproportionate high impact from flight activity at Logan.

This section describes the differences in runway use patterns for the Preferred Alternative and the No Action Alternative. The analysis will describe effective jet utilization[6], which weights nighttime operations ten times more heavily than daytime operations. This weighting reflects how noise is perceived by the public and thus is a key input for estimating in-flight noise impacts.

4.6.5.1 Annual PRAS Goals

Without airfield improvements, air traffic controllers will have fewer runway options as activity at Logan increases, limiting their ability to follow preferred runway use procedures. As illustrated in Table 4.6-5, without Runway 14/32 the percentage of effective jet operations impacting populated areas to the northeast and west of Logan is projected to increase from 69 percent in 1998 up to 82 percent in the 37.5M High Fleet scenario. By providing an additional three-runway configuration with a northwest orientation, unidirectional Runway 14/32 would permit a more balanced distribution of operations by direction. In the 37.5M High Fleet scenario, the effective jet utilization of runways affecting communities to the north and south would decline from 82 percent to 57 percent with the

▼

6 Effective jet utilization excludes non-jet operations and weights nighttime jet operations, operated from 10:00 PM to 7:00 AM, by a factor of 10.

availability of unidirectional Runway 14/32. In addition, effective jet activity to the southeast or over the water would increase from 13 to 26 percent with unidirectional Runway 14/32.

Table 4.6-5
Distribution of Effective Jet Aircraft Operations by Operating Direction

		37.5M High Fleet	
Direction	1998	Alternative 4 No Action	Alternative 1A Preferred Alternative
North and South	69%	82%	57%
East (Overwater)	21%	13%	26%
West	10%	5%	17%
Total	100%	100%	100%

A summary of effective jet aircraft runway use for the 1993, 29M Low and 37.5M High Fleets is presented in Table 4.6-6 for arrivals and Table 4.6-7 for departures. The information for the future scenarios is also presented graphically in Figures 4.6-4 and 4.6-5 (Appendix H of the Airside Project Draft EIS/EIR included effective jet runway use for the 29M High, 37.5M Low, and 45M High Fleets. Also see Appendix B of this Supplemental DEIS/FEIR for the 1998 Fleet).

In all future forecast scenarios, the Preferred Alternative increases operations over water and achieves a more balanced distribution of operations over land because it includes Runway 14/32. For example, in the 29M Low scenario, the Preferred Alternative increases equivalent jet arrivals for Runways 15R, 32 and 33L compared to Alternative 4 (No Action). In the same scenario, equivalent jet arrivals on Runway 4R, which occur over land and impact the South Boston and South Shore communities, are reduced significantly. In terms of departures, the Preferred Alternative causes an increase in equivalent jet utilization for Runways 14 and 15R (overwater) and a significant reduction for Runway 9, which impacts the Point Shirley community.

Percent of Equivalent Operations on Runway

The Preferred Alternative offers a dramatic improvement in overall annual PRAS goal achievement, and by providing reduced approach minimums, also offers greater flexibility and improves PRAS goal achievement under poor weather conditions. The overall degree to which airfield operations approach annual PRAS goals for runway use at Logan can be measured in terms of the PRAS Performance Index (PPI) described previously in this chapter. A value of zero would represent perfect compliance with the PRAS goals, compared to the *1998 Annual Update* value of 997. An improvement in terms of the PRAS goals is expressed as a decline in the PPI, which means that lower values indicate better conformance (see Table 4.6-8).

For most runway ends, the Preferred Alternative provides closer achievement of the annual PRAS runway use goals. For some runway ends, such as 15R, greater compliance with the PRAS goals leads to an increase in effective jet utilization.

Table 4.6-8
Achievement of Annual PRAS Runway Use Goals

	PRAS Performance Index		
Improvement Concept	**1998 Historic**	**29M Low**	**37.5M High**
Perfect PRAS Compliance	0	0	0
Preferred Alternative - All Except Peak Period Pricing	59	147	480
Alternative 4 – No Action	997	731	2,803

4.6.5.2 Dwell and Persistence

The short-term PRAS goals include dwell (one-day) and persistence (three-day) goals. (See Section 4.3.2.2) The DELAYSIM model measures compliance with dwell and persistence goals in terms of annual hours in excess of the defined targets. It is important to note that increases in dwell or persistence for overwater areas actually represent benefits since this results in a corresponding decrease in the total hours of flying over more populated areas.

The addition of Runway 14/32 and the reduced approach minimums on Runways 15R, 22L, 27 and 33L result in substantial benefits, with significantly fewer hours of dwell over populated areas. Figures 4.6-6 and 4.6-7 illustrate annual hours of dwell exceedence by runway end for the 29M Low and 37.5M High Fleets.

Figure 4.6-6
Annual Hours of Dwell Exceedence by Noise Area – 29M Low Fleet Scenario (510,000 Operations)

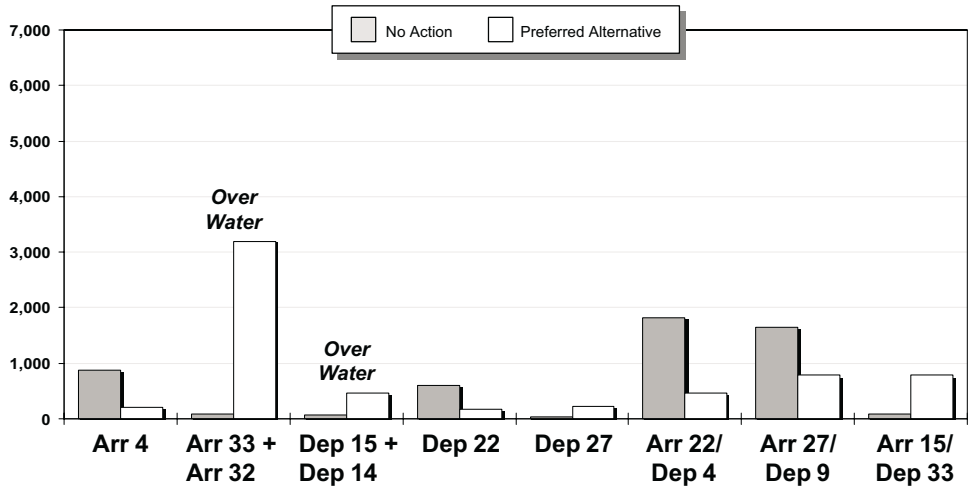

Figure 4.6-7
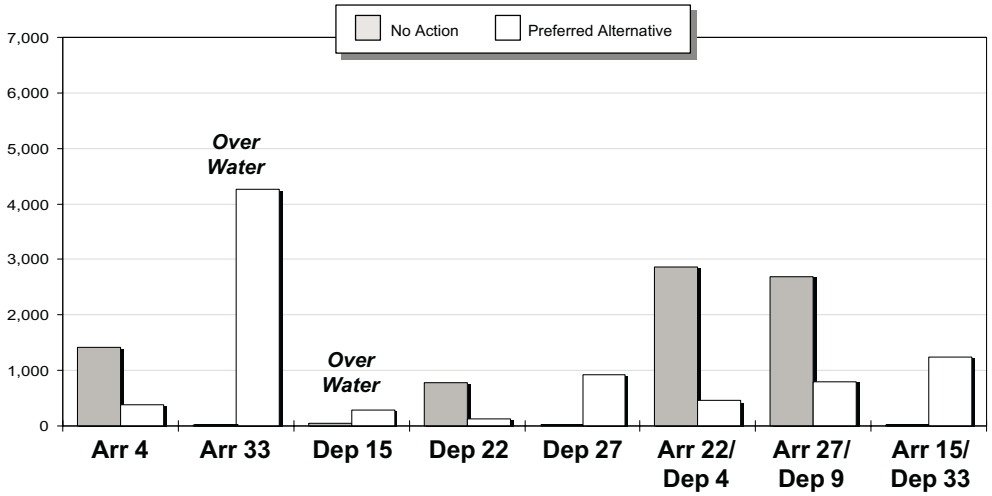
Annual Hours of Dwell Exceedence by Noise Area – 37.5M High Fleet Scenario (608,000 Operations)



The hours of persistence exceedence presented in Figure 4.6-8 and Figure 4.6-9 are consistent with those for dwell. As with dwell, the addition of Runway 14/32 results in significant improvements, particularly in the long-term scenario. A significant environmental benefit of Runway 14/32 is that hours of persistence exceedence for overwater areas increase dramatically (e.g., from 74 to 3,186 hours in the 29M Low Fleet for arrivals to Runway 33), while in most cases, persistence over populated areas and therefore perceived noise impacts is greatly reduced. Figures 4.5-8 and 4.6-9 illustrate annual hours of persistence exceedence by runway end for the 29M Low and 37.5M High Fleets.

Figure 4.6-8
Annual Hours of Persistence Exceedence by Noise Area – 29M Low Fleet Scenario (510,000 Operations)

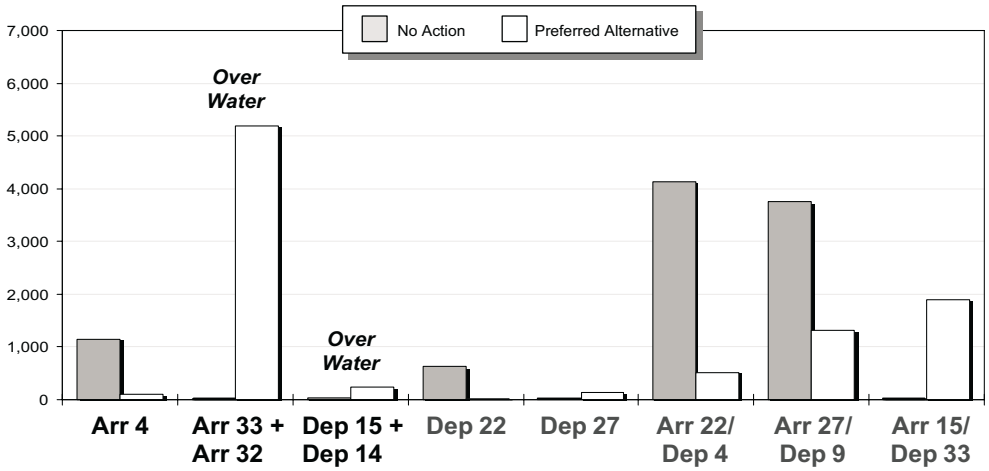


Figure 4.6-9
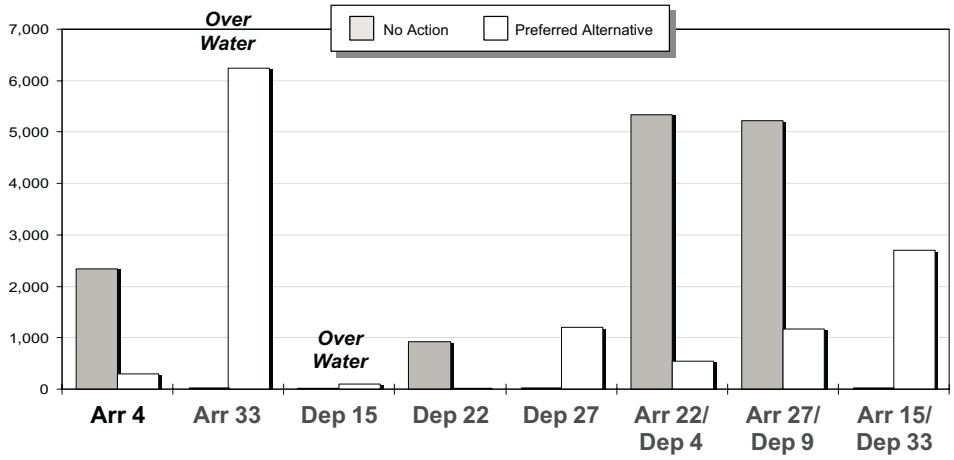
Annual Hours of Persistence Exceedence by Noise Area – 37.5M Low Fleet Scenario (608,000 Operations)



4.7 Aircraft Delay and Runway Use Results for High Regional Jet Scenario

The Logan airfield modeling methodology, described previously in this chapter and in Chapter 4 of the Airside Project Draft EIS/EIR, was also used to estimate runway delays and runway utilization for the new 37.5M High RJ Fleet described in Section 4.2. This analysis was identical to that discussed previously with the following three exceptions.

The High RJ scenario examined only the runway related delays. The Airside Project Draft EIS/EIR developed taxiway delays for a full range of future fleet scenarios. The taxiway delays comprise a relatively small fraction of the runway delays in every case, and there is no reason to expect that the taxiway delay savings for the High RJ fleet would differ in any significant manner from those of the other fleets (e.g., 15,000 to 20,000 annual hours).

Due to the nature of the High RJ fleet, the delay models were modified to allow the regional jets to be analyzed as separate classes. Thus, for example, the runway assignments and runway utilization statistics can extract the regional jets from the other conventional jets.

The largest change in the High RJ analysis was the use of newer weather data for estimating delays and runway utilization for this scenario. Several comments received on the Airside Project Draft EIS/EIR suggested that the 1981 through 1990 weather database used in the prior studies should be updated with later information. Analysis has shown that there have been no climatic changes since 1981-90 that could substantially alter the conclusions of the earlier studies, the FAA has recently augmented its weather database with the inclusion of wind gust observations that were not previously available. Since controllers and pilots normally consider wind gusts when selecting active runways at the airport, this newer data was adopted for the analysis of the 37.5M High RJ Fleet scenario. Because the enhanced weather data has only been available since 1997, the delay and runway use results for the High RJ Fleet scenario are based on a three-year weather period rather than the ten-year period employed previously. The general impact of the wind gust data is to reduce somewhat the availability of each runway configuration. This is because the wind speed with gusts is the same as or greater than without the gusts, so the cross-wind or tail-wind restriction will occasionally exclude a runway configuration that would otherwise be available. As a consequence of the wind gust data, the analysis of runway use and corresponding delays for the 37.5M High RJ fleet represents an improved estimate of actual operating practice at the airfield.

Since operational experience with regional jets is still relatively limited, there is no unanimity among pilots, controllers, airlines, airport operators and manufacturers as to their practical limitations. To assess the benefits of Runway 14/32 under different assumptions, a sensitivity analysis is presented in Section 4.7.3. The assumption adopted for the nominal analysis follows the suggestions in the *FAA Consultant Report of Regional Jet Utilization of Runway 14/32* in Appendix C: all Dornier model RJs will be able to land on Runway 32; all Embraer model RJs will be able to land on Runway 32 in dry conditions (but not when the runways are wet); and Canadair models will not use Runway 32.

The final refinement in the 37.5MHigh RJ Fleet analysis was an assessment of the potential impacts of an effective Peak Period Pricing program. Because regional jets are generally far more profitable than non-jets, the flat-fee peak period pricing program used with the other fleets was ineffective. The following section describes that analysis and the projected impacts of an effective program.

4.7.1 Peak Period Pricing Program with the 37.5M High Regional Jet Fleet

The initial Peak Period Pricing analysis for the 37.5M High RJ Fleet scenario followed the general approach used to evaluate this demand management mechanism under the other tested fleet scenarios. This approach is described in Section 4.5 of this chapter.

The fleet mix changes reflected in the 37.5M High RJ Fleet scenario have significant implications for a successful Peak Period Pricing program at Logan. First, the 37.5M High RJ Fleet includes a substantial number of regional jet operations and a greatly reduced, but still significant volume of non-jet regional carrier aircraft. It is the combination of these two aircraft types that poses the greatest problem for a flat-fee based Peak Period Pricing Program. The larger and faster regional jets are operating in markets of longer distance, higher revenue and greater profit than their non-jet predecessors, and will be less susceptible to the economic disincentive represented by the flat $150 surcharge. A flat fee large enough to impact peak period regional jets would threaten the economic viability of non-jet services, and could result in the elimination of non-jet operations at Logan, despite the exemption program.

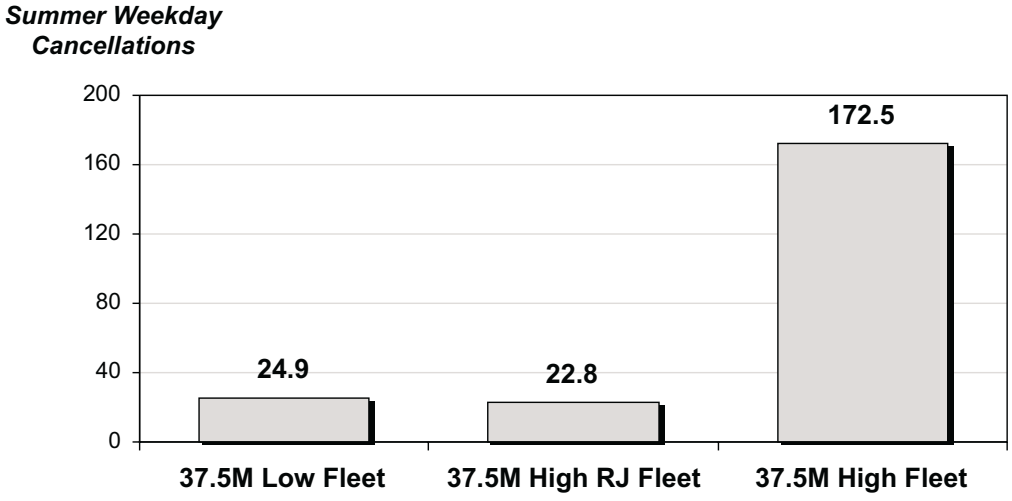
Table 4.7-1 compares estimated revenues and profit levels for several illustrative Logan markets served by either regional jets or conventional non-jet aircraft. It shows that the profit level achieved on a typical regional jet route can be significantly greater than the profit associated with a non-jet service. Whereas a $150 fee could easily eliminate the profitability of a non-jet flight, particularly those operated with the smallest 9- and 19-seat aircraft, a surcharge of this magnitude is unlikely to represent a meaningful deterrent to an operator of regional jet aircraft.

It is therefore not surprising that the analysis of a $150 peak surcharge on the 37.5M High RJ Fleet shows only a limited impact on carrier flight schedules and the resulting Logan demand profile. Figure 4.7-1 compares the number of daily flight cancellations (summer weekday) predicted for the 37.5 million passenger fleets. The 23 daily flight cancellations estimated for a summer weekday in the 37.5M High RJ scenario are far below the predicted impact on the 37.5M High Fleet, and even below the levels estimated for the 37.5M Low Fleet. Based on previous analysis of the delay impacts associated with Peak Period Pricing under the Low Fleet scenario, it was apparent that the predicted schedule changes caused by a $150 peak fee on the 37.5M High RJ Fleet would not produce a meaningful reduction in delays.

Table 4.7-1
Impact of a $150 Peak Period Surcharge on Turboprop and RJ Markets

Aircraft Class and Market	Carrier	Aircraft Seat Size	Estimated Revenue Per Passenger	Revenue per Flight	Peak Fee	Peak Fee as a Percent of Revenue
Turboprop						
Nantucket	Cape Air	9	$85	$383	$150	39.2%
Portland	US Airways Express	19	$64	$608	$150	24.7%
Burlington	American Eagle	33	$93	$1,527	$150	9.8%
Regional Jet						
Norfolk	American Eagle	37	$193	$3,939	$150	3.8%
Philadelphia	Delta Connection	50	$142	$3,910	$150	3.8%
Indianapolis	US Airways Express	50	$177	$4,858	$150	3.1%
Richmond	US Airways Express	50	$186	$5,106	$150	2.9%

Figure 4.7-1
Comparison of Impacts of a $150 Surcharge on 2015 37.5M Fleet Scenarios – 37.5M Low vs. 37.5M High RJ vs. 37.5M High

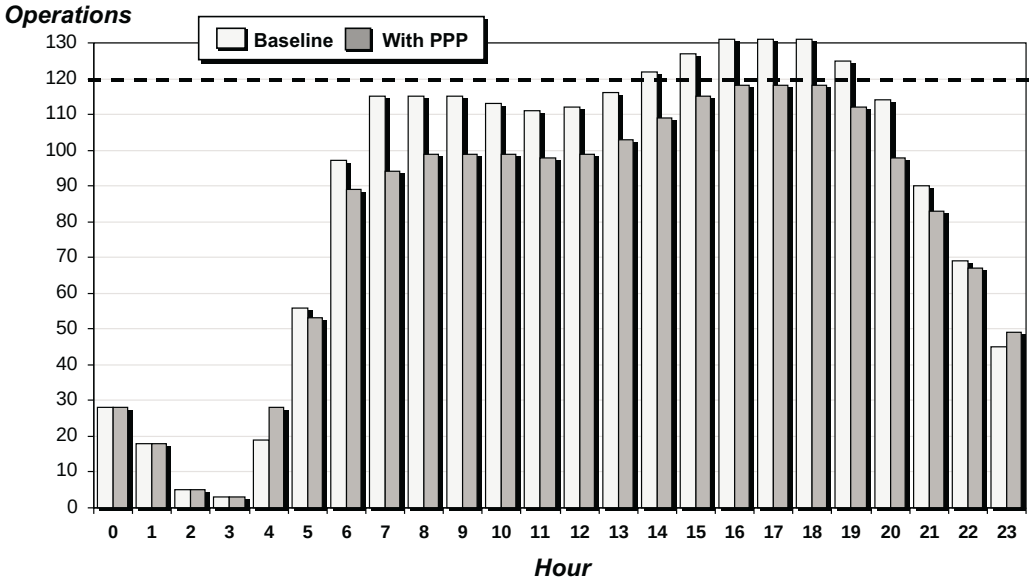


To structure a Peak Period Pricing regimen that would succeed in eliminating airline overscheduling in an environment such as the 37.5M High RJ Fleet scenario, it would be necessary to charge a substantially higher peak period surcharge. In addition to the risk of eliminating non-jets at Logan, a sufficiently high peak surcharge could produce a large surplus in airfield revenues, thereby violating the principle of revenue neutrality.

The FAA is currently evaluating alternative demand management mechanisms to replace the interim slot lottery at New York LaGuardia (see Chapter 3). Clearly, any strategy to eliminate excess airline demand at LaGuardia will have to deal with the high level of regional jet demand that emerged following passage of Air-21 in March 2000. In addressing the LaGuardia situation, the FAA may provide guidance on issues such as revenue neutrality and a mechanism to permit a continuation of turbo-prop services from small and medium-size communities. With the pending decision at LaGuardia, it is premature at this time to define the specific parameters for an effective program at Logan. Rather, these parameters will be more effectively defined at the time of implementation, following an FAA rulemaking at LaGuardia and when the specific fleet characteristics of Logan's overscheduling situation are known.

It is possibile, however, to postulate what the results of an effective Peak Period Pricing program would be in terms of the program impacts on Logan's hourly demand profile. For example, in the 37.5M High Fleet scenario, Peak Period Pricing provided significant delay reduction benefits by reducing hourly flight volumes to a level below Logan's normal operating capacity of approximately 120 flights per hour. The impacts of the illustrative program on the summer demand profile for the 37.5M High Fleet scenario are shown in Figure 4.7-2.

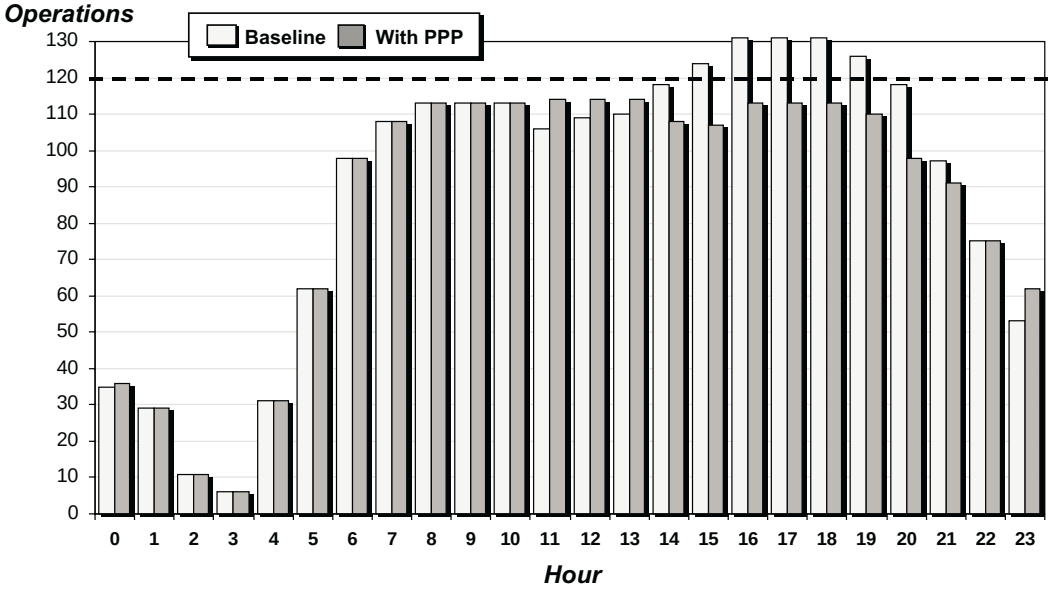
Figure 4.7-2
Comparison of August Weekday Peaking Patterns – 37.5M High Fleet (Maximum 3-Hour Average)



The operational and environmental analysis for Peak Period Pricing on the 37.5M High RJ Fleet was structured based on projected impacts to Logan's demand profile that were comparable to those produced under the 37.5M High Fleet scenario. Figure 4.7-3 illustrates the demand profiles for a representative summer weekday that were developed to reflect the projected impacts of an effective Peak Period Pricing program on the 37.5M High RJ Fleet. It shows that the peak activity level for the busiest three-hour period is reduced from 131 flights per hour down to 114 hourly flights, and that operation levels are consistently below Logan's full operating capacity of 120 flights per hour. The changes in the profile are equivalent to approximately 18,000 annual cancellations (or 10.5 percent of the total peak period flights).

The demand profile described above, and the fleet mix associated with that demand profile, were inputs to the capacity and delay modeling for the 37.5M High RJ alternatives that included Peak Period Pricing (Alternatives 1, 2, and 3). The results of this Peak Period Pricing delays analysis are described along with the delay reduction benefits of the Preferred Alternative in the following sections.

Figure 4.7-3
Comparison of August Weekday Peaking Patterns – 37.5M High RJ Fleet (Maximum 3-Hour Average)



4.7.2 Runway Delays

The results of the 37.5M High RJ Fleet runway delay analysis are similar to those for the other future year operating conditions. Table 4.7-2 compares the results of the runway delay analysis for the four alternatives under the 37.5M High Regional Jet scenario. The table indicates that Logan will incur extremely high levels of delay if no actions are take to improve airport operating efficiency. For the No Action Alternative (Alternative 4), Logan passengers and airlines are forecast to experience over 370,000 annual hours of delay. With the Preferred Alternative, these runway delays are reduced by 29% to 263,000 hours, demonstrating the effectiveness of Runway 14/32. Analysis with the proposed Peak Period Pricing monitoring program indicates that the 37.5M High RJ Fleet would trigger implementation of a peak period pricing program, and under Alternative 1 (All Improvements), runway delays would be further reduced to 219,000 annual hours. This additional benefit demonstrates the effectiveness of a peak period pricing program under overscheduling conditions.

Table 4.7-2
Total Hours of Runway Delay by Alternative

Alternative	37.5M High RJ Fleet
Total Delay	
Alternative 1 – All improvements	219,200
Preferred Alternative - All except Peak Period Pricing	263,500
Alternative 2 – All except Runway 14/32	304,300
Alternative 4 - No Action	372,200
Delay Reduction	
Alternative 1 vs. Alternative 4	**153,000**
Preferred Alternative vs. Alternative 4	**108,700**
Alternative 3 vs. Alternative 4	**67,900**

Figure 4.7-4 shows the forecast distribution of runway delays between VFR (Visual Flight Rules) and IFR (Instrument Flight Rules) weather conditions. With the High RJ Fleet, approximately fifty percent of the modeled No Action delays occur in IFR conditions. While the proposed improvements have relatively little impact on IFR delays, VFR delays decline significantly with the airside improvements.

Figure 4.7-4
Annual Delay Hours by Weather Condition

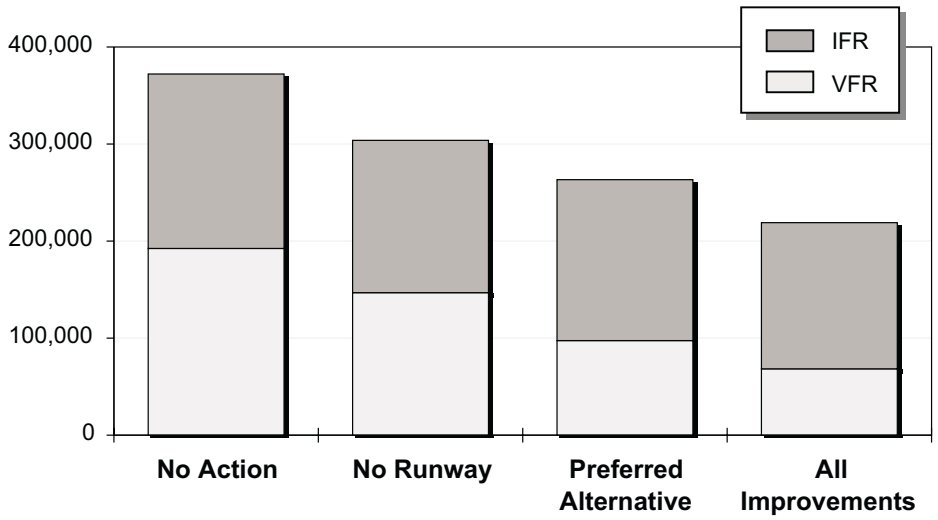


Figure 4.7-5 depicts VFR delays categorized by wind direction. A comparison of the No Action and Preferred Alternative indicates that Runway 14/32 would reduce VFR northwest wind delays by 65 percent.

4.7.3 Runway Use

The effects of the Airside Improvements on runway use for the High RJ Fleet are also similar to those presented previously for the other future scenarios.

Table 4.7-3 shows the total jet operations by operating direction for 1998 and the projections for the 37.5M High RJ Fleet. Without unidirectional Runway 14/32, the north/south communities' share of overflights would grow to 90 percent from the 76 percent that occurred in 1998. With the Preferred Alternative, jet overflights of the north/south communities decline to 58 percent. At the same time, the Preferred Alternative would increase the overwater flights by a factor of four versus the No Action scenario and would produce a much more balanced and equitable distribution of overflights. Peak period pricing would not help the disproportionate impact on the north/south communities.

Figure 4.7-5
VFR Delay Hours by Wind Direction

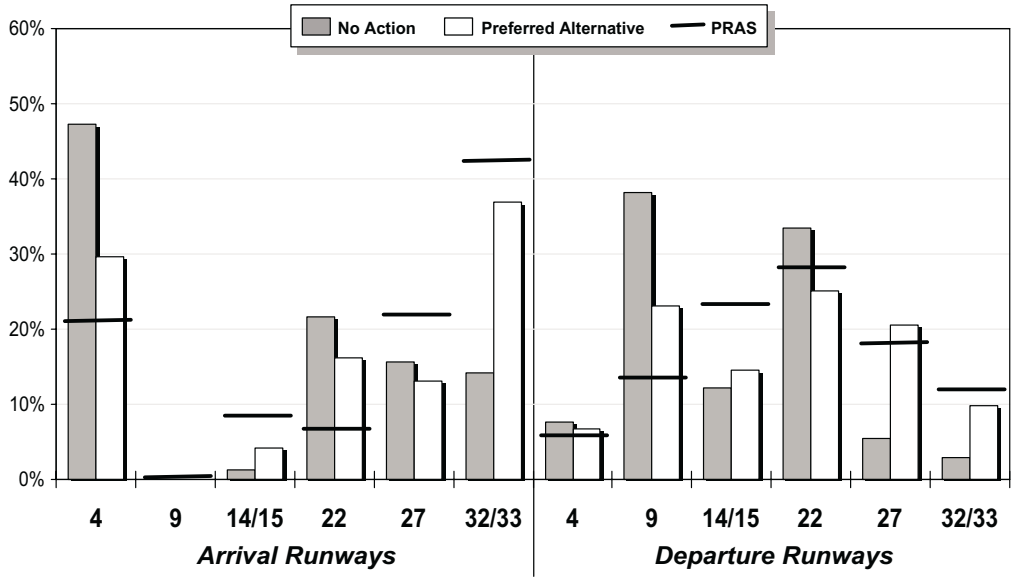

Table 4.7-3
Distribution of Jet Operations by Operating Direction

		37.5M High RJ Fleet			
Direction	1998	Alternative 4 No Action	Alternative 1A Preferred Alternative	Alternative 1 All Actions	Alternative 2/3 No Runway
North and South	76%	90%	58%	57%	91%
East (Overwater)	13%	6%	22%	22%	5%
West	11%	4%	21%	21%	4%
Total	100%	100%	100%	100%	100%

4.7.4 PRAS Goals

This section describes how the differences in runway use patterns provided by the Airside Improvements would produce an overall improvement in future compliance with the annual and short-term PRAS goals under the 37.5M High RJ scenario.

4.7.4.1 Annual Runway End Use Goals

As discussed previously, the annual PRAS goals use effective jet utilization[7] which weights nighttime operations ten times more heavily than daytime operations. Table 4.7-4 compares the effective jet utilization for 1998 and the four modeled alternatives of the 37.5M High RJ Fleet.

Table 4.7-4
Distribution of Effective Jet Operations by Operating Direction

		37.5M High RJ Fleet			
Direction	1998	Alternative 4 No Action	Alternative 1A Preferred Alternative	Alternative 1 All Actions	Alternative 2/3 No Runway
North and South	69%	84%	60%	59%	83%
East (Overwater)	21%	11%	23%	24%	12%
West	10%	5%	17%	17%	5%
Total	100%	100%	100%	100%	100%

Without unidirectional Runway 14/32 the percentage of effective jet operations impacting populated areas to the north and south of Logan is projected to increase from 69 percent in 1998 up to 84 percent in the 37.5M High RJ Fleet scenario. The Preferred Alternative increases overwater flights and achieves a more balanced distribution of operations over land. For example, the, Preferred Alternative more than doubles equivalent jet operations over Boston Harbor, while reducing them over the northern and southern communities by 29 percent. The effective jet utilization of runways affecting communities to the north and south together would decline to 60 percent (less than 1999's 68 percent) with the availability of Runway 14/32. Moreover, by reducing delays at the airfield which shift some flights into the nighttime hours, the Preferred Alternative would also yield an 8 percent reduction in total effective jet operations. Peak Period Pricing (Alternative 1) would provide a slight additional reduction in total effective jet operations by canceling a few regional jet flights, but by itself (Alternatives 2/3) would not permit any relief to the northern and southern communities.

Tables 4.7-5 and 4.7-6 compare the effective jet utilization of the four Airside Improvement alternatives with 1998 actual use and with the PRAS annual goals, while Figure 4.7-6 presents the 37.5M High RJ runway end use graphically. The Preferred Alternative offers a dramatic improvement in overall annual PRAS goal achievement. The PRAS Performance Index (PPI) described previously in this chapter shows that the Preferred Alternative improves PRAS conformance by a factor of 2.7 (see Table 4.7-7).

▼

7 Effective jet utilization excludes non-jet operations and weights nighttime jet operations, operated from 10:00 PM to 7:00 AM, by a factor of 10.

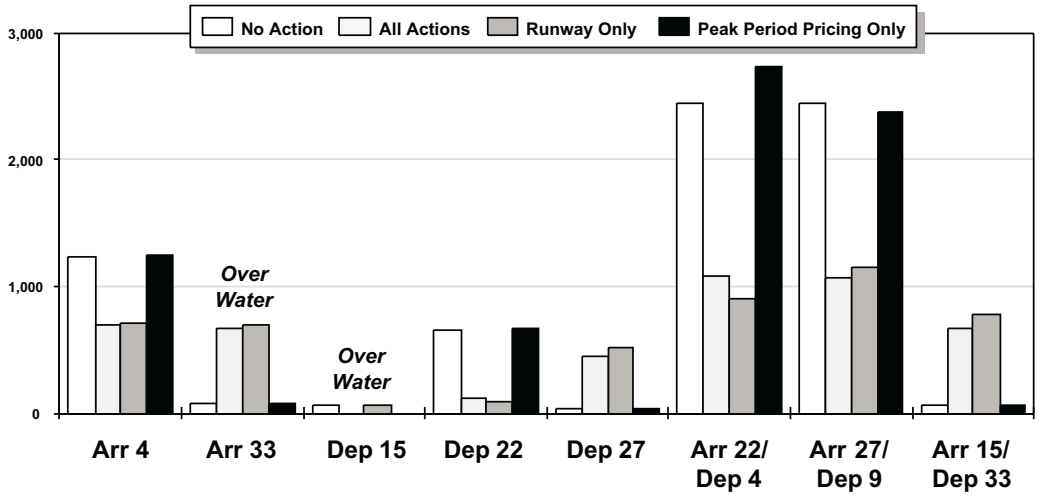
4.7.4.2 Dwell and Persistence

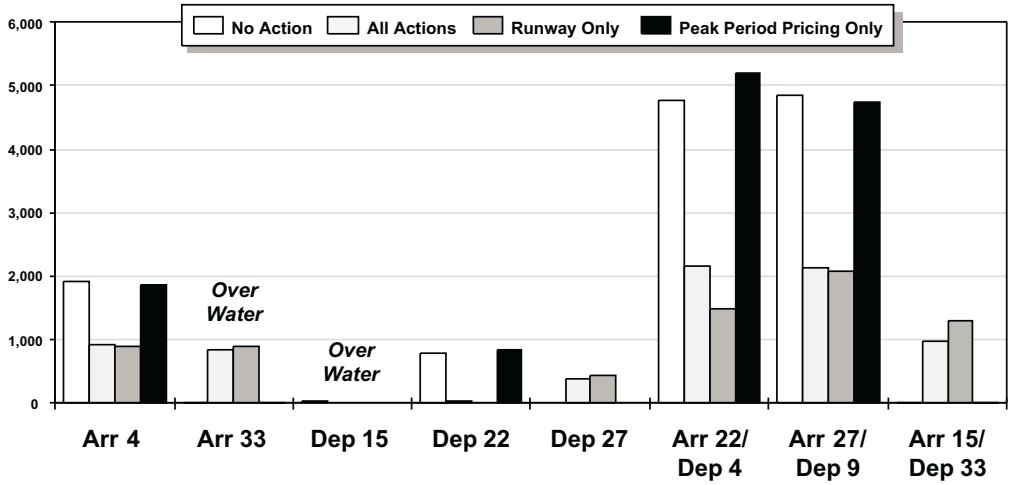
Figure 4.7-7 presents the annual hours of dwell exceedence for the High RJ scenario by runway end for each improvement alternative. The addition of Runway 14/32 and the reduced minimums of the Preferred Alternative result in substantial short-term noise benefits, with 30 percent fewer total hours of dwell over populated areas. Peak period pricing, either alone or with the runway, does not produce any significant changes in dwell. With the runway, communities to the north (A22/D4 and A27/D9) and south (A4 and D22) experience substantial short-term noise relief, while the overwater zones (A33/32 and D15/14) receive more dwell. Dwell also increases for populated areas to the west (D27), but those communities still receive less impact than the north and south populations, and total exposure is reduced.

Figure 4.7-7
Dwell Exceedence by Noise Area – 2010 37.5M High RJ Fleet
Annual Hours of Dwell Exceedence



The annual hours of persistence exceedence are presented in Figure 4.7-8 by runway end and alternative. The results are generally consistent with those for dwell, but the magnitude of the benefits are even greater. The Preferred Alternative reduces total persistence exceedence by 42 percent, or 49 percent if overwater areas are excluded. Peak period pricing actually increases the persistence exceedence slightly. Although communities to the west receive a moderate increase in persistence exceedence with the Preferred Alternative, the level is far less than that suffered by the north or south communities.

Figure 4.7-8
Persistence Exceedence by Noise Area – 2010 37.5M High RJ Fleet
Annual Hours of Persistence Exceedence



4.7.5 Sensitivity to Regional Jet Runway Use

The 37.5M High RJ Fleet scenario was developed to assess the potential impact of regional jet aircraft on the future utility of the proposed Runway 14/32. The regional jets in this scenario comprise nearly one-third of the total flight operations. Of these, 55 percent are by Embraer models (ERJ), 24 percent by Dornier/Fairchild models (DRJ), and 21 percent by Canadair models (CRJ). A key factor in the operational evaluation was the ability of these new regional jets to land on a 5,000 foot runway. The airframe manufacturers specifications and the FAA type certifications indicate that the regional jets produced by all three makers are capable of landing in less than 5,000 feet over a 50-foot obstacle when the aircraft is at maximum gross weight, the runway is dry, there is no wind, and the temperature is below 60 degrees Fahrenheit. However, the conditions of each flight operation are different, and a fully loaded CRJ, for example, would not be able to land on 5,000 feet on a warm rainy summer day. On the other hand, few regional flights operate at maximum gross weight, and normally when Runway 32 is in use northwest winds will provide a headwind that can substantially reduce landing distances. Moreover, there is no obstacle on the approach end of Runway 32, and the length of the runway plus the safety areas on both ends add up to 7,000 feet of paved surface. When long delays exist on Runway 33L under strong northwest wind conditions, it is unlikely that many would reject the option of a perfectly safe and legal landing on Runway 32, particularly as they gain familiarity with the new runway.

The assumptions for regional jet use of Runway 32 were based on the analysis conducted by FAA's consultant that DRJs would use it under wet or dry conditions, ERJs would accept it under dry conditions, and CRJs would refuse it. (See Appendix C). This policy resulted in a 29 percent reduction in runway delays for the Preferred Alternative compared to the No-Action Alternative. To assess the sensitivity of delays to the possible regional jet utilization of Runway 32, two other cases were modeled. One extreme was to assume all

regional jets could and would use Runway 32 under all conditions. The other was to assume that only the DRJs would use the new runway. The results of the sensitivity analysis are presented in Table 4.7-8. Under the most optimistic assumption—that all regional jets use the runway—the incremental delay savings are 9,500 hours or just 2.6 percent more than the nominal 29 percent. The very pessimistic assumption that only the DRJs use Runway 32 still saves 76,400 hours of delay per year, or 21 percent less than would occur under the No Action scenario. The conclusion of the sensitivity analysis is that, depending on the regional jet use, Runway 14/32 will save between 76,000 and 118,000 hours of delay per year, with the best estimate being about 108,000 hours.

Table 4.7-8
Sensitivity of Delays to Regional Jet Use of Runway 32

	Runway 32 Assignment						Annual	Percent
	Dormier		Embraer		Canadair		Delay Hours	Delay
Alternative	Dry	Wet	Dry	Wet	Dry	Wet	Saved	Savings
No Action Alternative (Alt. 4)							N/A	
Preferred Alternative (Alt. 1A)								
Nominal (Base Case)	X	X	X				108,100	29.0%
High	X	X	X	X	X	X	117,600	31.6%
Low	X	X					76,400	20.5%

4.7.6 Northwest Wind Restriction on Use of Runway 32

One of the issues raised in the SDEIS Panel Process was the possibility of restricting the availability and use of Runway 32 to northwest wind conditions only. This concept was conceived as a potential limit on the increase in the number and proportion of jet departures on Runway 27 that was predicted to occur with construction of Runway 14/32. Runway 27 is the principal departure runway used in combination with arrivals on Runways 33 and 32 in the new three-runway configuration that would become available with construction of unidirectional Runway 14/32. With the proposed runway, Logan would have three-runway configurations available in three distinct operating directions: to the northeast using Runways 4L/4R and 9, to the southwest using Runways 22L/22R and 27, and to the northwest using Runways 33/32 and 27.[8]

Currently, when wind conditions require air traffic control to route aircraft on a northwesterly heading, available airfield capacity declines sharply from Logan's normal three-runway capacity down to the capacity of two, and sometimes just one runway. As described throughout this report, the construction of Runway 14/32 would prevent this

▼

8 Construction of the proposed new runway would also create a fourth three-runway configuration—Runways 15/14/ and 9—in a southeast alignment. However, this configuration would have limited arrival capacity.

substantial decline in airfield capacity, and the resulting aircraft delay that now occurs under these conditions.

The increased usage of Runway 27 projected in the airfield simulation modeling reflects the availability of this new three-runway configuration in the northwest direction. This configuration would not only allow controllers to nearly eliminate northwest wind delays at Logan, but would also enable air traffic control to more evenly distribute aircraft overflights across three different operating directions during periods of high demand. As discussed previously in this chapter, this flexibility leads to a significant improvement in the ability of air traffic control to achieve the Preferential Runway Assignment System (PRAS) goals and provides relief to residents of communities impacted by use of the existing north and south runway configurations.

The full analysis of the proposed northwest wind restriction on Runway 32 is presented in Appendix D of this Supplemental DEIS/FEIR. Major findings are summarized below.

4.7.6.1 Summary of Results for a Northwest Wind Restriction on Runway 32

A northwest wind restriction would sacrifice a portion of the delay reduction benefits that could be realized through unrestricted usage of unidirectional Runway 14/32. Even at the least severe 5-knot wind restriction, Logan would experience 17,000 more hours of annual aircraft delay under the 37.5M High RJ Fleet scenario than it would with an unrestricted runway. As the wind speed criterion is increased, further limiting the circumstances in which Runway 14/32 could be used, the delay benefits of the proposed runway are progressively eroded.

The proposed restriction does limit the increase in jet departures off Runway 27 that results from its use in combination with Runways 33L and 32. With a 5-knot northwest wind restriction, usage of Runway 27 declines from 29 percent to 18 percent of total Logan jet departures.

However, the decreased usage of Runway 27 corresponds with other, less desirable changes in runway utilization at Logan. Restrictions on the use of Runway 32 would limit the number of aircraft using over-the-water routings to Runways 32 and 33L. The proposed restriction also sacrifices potential relief to residents of communities impacted by the prevailing north/south runway configurations at Logan.

Restricting the use of Runway 32 would reduce the ability of air traffic controllers to achieve the PRAS goals, including the annual runway use goals and the short-term goals designed to limit dwell and persistence of overflights impacting individual communities.

A wind restriction on the use of Runway 32 would increase the number of people exposed to the highest noise levels above 70 DNL (compared to an unrestricted runway). However, the restriction would at the same time lower the population exposed to noise levels greater than 65 DNL. These impacts occur due to changes in runway utilization patterns that result from restricting the use of Runway 32.

4.8 Conclusion

Logan is currently the sixth most delayed airport in the United States, and experienced approximately 142,000 hours of total aircraft delay in 1998. If no improvements are made at Logan, continuing growth in demand for air transportation services will be accompanied by a significant increase in delays. Conversely, the Preferred Alternative represents an effective means to minimize the growth in delays, enhance safety, allow for better achievement of PRAS goals, and increase the number of flights over water.

The delay reduction benefits attributable to the various Airside Project Alternatives were assessed against a range of potential future fleet scenarios. This analytic approach provides an understanding of the circumstances under which individual improvement concepts are most effective, and how their contribution may vary according to future operating conditions at Logan. The analysis demonstrated that Alternatives that include Runway 14/32 provide a significant reduction in delay in both the near- and longer-term operating environment at Logan. Delay reduction benefits associated with the Preferred Alternative range from 21 percent (or 28,000 annual hours) under the 29M Low Fleet, to 29 percent (or 109,000 hours) under the 37.5 M High Fleet scenario. The greatest benefits occur during VFR weather conditions when the availability of Runway 14/32 would reduce future delays by approximately 50 percent or more.

Unidirectional Runway 14/32 reduces delays by enabling Logan to maintain its normal three-runway capacity when wind conditions require operations in the northwest direction. Since operations in turboprops have declined and regional jets have entered the fleet, commenters questioned the utility of the proposed runway. Even though the unidirectional Runway 14/32 is only 5,000 feet long, the FAA consultant evaluated the probable utilization by regional jets and found that the runway length would be acceptable for most future RJ's at Logan.

Runway 14/32 would be permitted and operated as a unidirectional runway, with all arrivals and departures occurring over Boston Harbor. As a result, 52,000 jet flights, or 17 percent of total jet operations for the 29M Low Fleet, would shift from flight paths over communities to flight paths over the water. By establishing an additional three-runway configuration at Logan, Runway 14/32 would provide greater flexibility in runway selection. This increased flexibility will permit a substantial improvement in the achievement of the annual PRAS runway use goals, designed to produce an equitable distribution of impacts across surrounding communities.

Incorporating a northwest wind restriction on Runway 32 would limit the increase in jet departures on Runway 27 that results from the availability of an additional three-runway configuration at Logan. However, this restriction would sacrifice a portion of the delay reduction benefits provided by the runway, and would also limit the relief provided to communities affected by the north/south runways which are already the most heavily utilized at Logan.

The Centerfield Taxiway and other proposed taxiway improvements provide consistent delay reduction benefits across future fleet scenarios by increasing the efficiency of Logan's taxiway system and reducing aircraft taxi delays by 47 percent with the 29M Low Fleet and 26 percent with the 37 M High Fleet (Alternative 2 vs. Alternative 3). The runway and taxiway improvements also enhance operational safety at Logan by reducing congestion on the ground and lowering the potential for runway incursions or wingtip conflicts.

Reduced minimums provide some delay reduction benefits and enhance safety by increasing runway availability options in Instrument Flight Rules (IFR). Reducing minimums do not change the flight path of arriving flights, but move the decision point for missed approaches closer to the airport, or over the airport. Reducing minimums will permit pilots to operate on optimal runways during crosswind conditions. While reduced minimums result in a modest annual delay reduction benefit, they are particularly effective during IFR weather conditions.

Peak Period Pricing is designed to reduce delays resulting from airline overscheduling which occurs when flight demand exceeds Logan's normal VFR capacity. Current and expected near-term demand patterns at Logan do not exhibit an overscheduling condition. In this environment, Peak Period Pricing would produce marginal delay reduction benefits while imposing heavy economic costs on regional carriers and small communities.

The illustrative Peak Period Pricing program with a $150 surcharge was ineffective at reducing delays under the 37.5M High RJ Fleet scenario. A higher peak fee would be required to provide meaningful delay reduction under this fleet scenario, principally due to the higher revenue and profitability of regional jet services as compared with non-jets. An effective Peak Period Pricing program that eliminates overscheduling in the High RJ Fleet was projected to reduce runway delays by approximately 68,000 annual hours or 18 percent (Alternative 2/3). While not recommending Peak Period Pricing for current implementation at Logan, Massport is establishing a schedule monitoring system to determine if and when to initiate curative action, which would lead to the implementation of Peak Period Pricing if necessary. As a first step in its curative action plan, Massport will initiate collaborative discussions with individual Logan carriers aimed at improving scheduling efficiency at Logan and postponing or eliminating the potential future emergence of airline overscheduling conditions. Massport is also anticipating guidance from the FAA as to key elements of a Peak Period Pricing program as the FAA addresses this issue at LaGuardia over the next several months.

Supplemental Draft Environmental Impact Statement/
Final Environmental Impact Report

Volume 2

5 Affected Environment

Key Points

In the Airside Improvements Planning Project Draft Environmental Impact Statement/Environmental Impact Report (Airside Project Draft EIS/EIR), Chapter 5 presented an overview of the baseline environmental conditions within the airport and surrounding communities. In this chapter of the Supplemental Draft Environmental Impact Statement/Final Environmental Impact Report (Supplemental DEIS/ FEIR), the analysis of baseline conditions was expanded to include analyses of the current environmental conditions that were presented in the *1998 Annual Update*.[1] This chapter also includes a description of historic properties and parklands within the Project impact area (this material was previously contained in Chapter 8 of the Airside Project Draft EIS/EIR) to support the analysis of potential impacts under Section 4(f) of the Department of Transportation Act, and under Section 106 of the National Historic Preservation Act of 1966, as amended.

This Supplemental DEIS/FEIR adds to the analysis included in the Airside Project Draft EIS/EIR by including 1998 Existing Conditions in comparison to 1993 Historic Modeled Conditions. The 1998 Existing Conditions are based on the findings of the *Logan Airport 1998 Annual Update*[2] to the *Logan Airport 1994/1995 Generic Environmental Impact Report* (GEIR)[3].

Noise

- Winthrop and East Boston are most affected by noise exposure from Logan operations, with significant numbers of residents experiencing noise greater than 70 decibel (dB) Day-Night Sound Level (DNL), and some experiencing it at levels above 75 dB DNL. South Boston and Revere are generally next most affected. Exposures at these highest noise levels support the continuing need to improve compliance with PRAS goals that attempt to reduce exposure in the most highly exposed areas without significantly increasing the exposure above 65 dB DNL in other areas.

- Nighttime noise levels determined from Time-Above calculations for both the 1993 modeled historic and the 1998 actual operations indicate that the most affected areas are Loring Road near Court, Somerset and Johnson, and Bay View

1 *Boston Logan International Airport, 1998 Annual Update,* October ,1999.
2 *Ibid*.
3 The Logan Airport Generic Environmental Impact Report is now known as the Environmental Status and Planning Report (ESPR). The 1999 ESPR was filed with the Executive Office of Environmental Affairs, MEPA Office on December 15, 2000.

and Grand View, all in Winthrop, and Bayswater and Nancia Roads and the East Boston Yacht Club in East Boston. These same sites also experience some of the highest DNL values of any locations around Logan.

- When comparing the noise-exposed population within the 65 dB DNL noise contours for the 1993 and 1998 scenarios, overall the 1993 historic modeled scenario includes approximately 34,400 people, while the 1998 actual condition includes 23,300 people. Almost all of this difference occurs northwest of Logan in East Boston and Chelsea. It is attributable to a variety of factors including 1993s use of 10 years of weather data and modeled, rather than actual, air traffic conditions, and a higher percentage of Stage 3 compliant aircraft.

- Noise exposure from aircraft taxi operations is significantly less than that for in-flight operations, especially during conditions of average sound propagation. However, for maximum propagation the ground taxi DNL is close enough to that for in-flight noise that it can add 1 to 2 dB to the closest receptors. The highest ground taxi noise appears to be at the three receptors around the northeast corner of the airport which are exposed to the noise from aircraft taxiing to take off on Runways 22L and 22R and to return to the terminals after landing on 4L and 4R. The areas are: Loring Road near Court, Winthrop, and Bayswater and Shawsheen Roads and the East Boston Yacht Club, both in East Boston.

Air Quality/Odors

- Measured air quality at Logan is within national and state ambient air quality standards. The Boston metropolitan area has experienced past violations that caused this area to be designated nonattainment for ozone.

- As documented in the *1998 Annual Update* ground service equipment (GSE) constitute the largest source of carbon monoxide (CO) emissions, representing over 43 percent of the Logan total. However, Massport and several major air carriers at Logan are undertaking programs to convert GSE to alternative fuels where feasible. Aircraft closely follow at approximately 42 percent. Airport-related motor vehicles are the third largest source, and other sources have a nearly negligible contribution.

- As in the 1993 historic modeled inventory, in 1998 aircraft emitted the largest portion (80 percent) of oxides of nitrogen (NOx). GSE are responsible for about 10 percent, while motor vehicles and other sources each emit almost 5 percent of the total.

- In 1998, volatile organic compounds (VOCs) emitted by aircraft constitute around 58 percent of the total, followed by GSE at roughly 18 percent. The remainder is divided between motor vehicles (11 percent) and other sources (13 percent).

Drainage and Water Quality

- The Preferred Alternative would be constructed in an area served by an existing stormwater collection and treatment system. Existing airfield stormwater runoff was found to be generally uncontaminated.

Soils

- The Airside Project Draft EIS/EIR identified a potential need to remove up to approximately 240,000 cubic yards of soil material stockpiled on Governors Island for construction of proposed Runway 14/32 (Alternatives 1 and 1A). Since circulation of the Airside Project Draft EIS/EIR, portions of the Governors Island soil stockpile were moved to the Town of Middleton's landfill, in response to a request from the court-appointed receiver for the landfill closure. As a result, there no longer will be a need to remove any of the Governors Island soil stockpile for construction of Runway 14/32.

- Other soil materials which may need to be excavated for taxiway and runway construction can be handled with conventional soil management procedures.

Habitat

- The Preferred Alternative is located in upland areas of the airfield which are generally vegetated by common grassland species. No portion of the Project is proposed within wetland resource areas.

Endangered and Threatened Species

- The upland sandpiper, a State-listed endangered species, has been observed on portions of the airfield to be used for the Preferred Alternative.

Coastal Zone Management Consistency

- In accordance with state and federal regulations, construction projects within the Coastal Zone must be consistent with the policies and principles established for these areas by the Massachusetts Office of Coastal Zone Management (MCZM). Discussion of the consistency criteria is included in Chapter 6, Environmental Consequences.

Parklands and Historic Resources

- Cultural resources including historic resources and parklands which are regulated under Section 4(f) of the Department of Transportation Act, the National Historic Preservation Act ("Section 106"), and by state regulations concerning historic properties are not impacted by the Preferred Alternative. As specified in the May 7, 1999 EOEA Certificate, parklands addressed include the Boston Harbor Islands, Arnold Arboretum, Franklin Park, and the Emerald Necklace.

Other

- The Preferred Alternative is located on an existing airfield and does not alter existing land use patterns. Likewise, the Preferred Alternative will not affect light emissions, floodplain, wild and scenic rivers, economic issues, farmland, energy supply, design and architecture or energy supply.

5.1 Introduction

The Federal Aviation Administration (FAA) directive[4] which implements the National Environmental Policy Act (NEPA) identifies categories of impact that are typically analyzed in an Environmental Impact Statement (EIS). The directive also indicates that analyses should be focused on areas in which impacts are likely, rather than areas where no impact or nominal impact is anticipated. Similarly, the Massachusetts Environmental Policy Act (MEPA) scope for the Logan Airside Improvements Planning Project (Airside Project) also focuses the environmental analysis on specific areas of potential impact. Chapter 5 describes environmental resources that may be affected by the Airside Project alternatives under consideration. Chapter 6, Environmental Consequences, presents an assessment of impacts of the Airside Project alternatives for both the construction and operations phases, while potential cumulative impacts are evaluated in Chapter 7.

5.1.1 Supplemental DEIS/FEIR Studies and Analyses

Additional studies and analyses conducted for this chapter of the Supplemental DEIS/FEIR are summarized below:

- This chapter describes noise conditions in the vicinity of Logan. It differs from the Airside Project Draft EIS/EIR in that it reports on the noise from a new operational scenario, the actual activity occurring in 1998 (as reported in the *Logan Airport 1998 Annual Update).*

- The noise analysis contains additional data in response to the Secretary of Environmental Affairs (EOEA) May 7, 1999 Certificate which requested Massport to extend the outer limits of its DNL and population analyses to the 60 dB DNL contour.

- A broader description is provided of cultural resources including historic resources and parklands which are regulated under Section 4(f) of the Department of Transportation Act, the National Historic Preservation Act ("Section 106"), and by state regulations concerning historic properties. As specified in the EOEA Certificate, parklands addressed include the Boston Harbor Islands, Arnold Arboretum, Franklin Park, and the Emerald Necklace.

[4] *FAA Environmental Handbook*, Order 5050.4A, October 8, 1985.

5.1.2 Affected Resources

As outlined in the EOEA Certificate[5] on the Airside Improvements Planning Project (Airside Project) Draft EIS/EIR, this Supplemental DEIS/FEIR is required to address the following categories of operational impacts: noise, air quality, and odor. This Supplemental DEIS/FEIR addresses those categories of operational impacts and also addresses impacts of more limited duration associated with construction of the alternatives, such as construction traffic. On-airport issues to be addressed by this Supplemental DEIS/FEIR consist of wetlands and vegetation, wildlife, water quality, soils management and relocation impacts to the South Cargo area of the airport. During the construction period, airport operations may also be affected. Background information provided in this chapter is used for detailed analysis of potential impacts presented in Chapter 6, Environmental Consequences, and summarized in Chapter 8, Preferred Alternative and Mitigation.

Due to the nature and location of the proposed Airside Project alternatives, there are several categories of resources that will not receive impacts, or would receive insignificant impacts. These are farmland, floodplains, wild and scenic rivers, light emissions and energy supply. There are no parklands, cultural resources, farmlands, or wild and scenic rivers on the airfield site; and no construction would occur in regulated floodplain areas. The lighting for proposed Runway 14/32 will be low to the ground and will be placed in accordance with FAA regulations for spacing and intensity. Therefore light emissions were not considered to have potential to create annoyance. Energy demands of the various alternatives would be within the capacity of available energy supply.

Categories in which impacts may potentially result have been identified for the Airside Project, and are discussed in the following sections.

5.1.3 Study Area

Logan Airport occupies approximately 2,400 acres, 700 acres of which are water, within the boundaries of the East Boston district of the City of Boston, Massachusetts and the Town of Winthrop, Massachusetts. The airport is surrounded by Boston Harbor on the east and south and on much of the north side as well. The East Boston neighborhoods of Jeffries Point, Eagle Hill, Harborview, and Orient Heights are west and northwest of the airport. The Town of Winthrop is east and northeast of the airport, separated by the waters of Boston Harbor. The Downtown Boston Central Business District is located to the west, and South Boston is located to the southwest across the Inner Harbor. (See Figure 5.1-1.)

[5] Secretary of the Executive Office of Environmental Affairs' on the Airside Improvements Planning Project Draft EIS/EIR, May 7, 1999. (See Responses to Comments, Volume 4).

The proposed Airside Project improvements are located on the existing airfield and do not alter existing land use patterns within the adjacent communities. Under FAA NEPA guidelines, the compatibility of existing and planned land uses in the vicinity of an airport is usually associated with the extent of noise impacts related to that airport. Land use ramifications are also evaluated concurrently with respect to other impact categories, such as wetlands, critical habitat of endangered and threatened species, or the disruption or relocation of communities.

In order to address both the broad concerns of surrounding communities and on-site issues, two study areas have been delineated: one which includes communities impacted by airport noise, as directed by FAA guidelines, and a second which consists of the Logan airfield.

5.1.1.1 Community Study Area

The community study area includes those areas within the 60 dB DNL noise exposure contour for airport-generated noise. While both the Department of Housing and Urban Development (HUD) and the FAA define an annual average DNL of 65 dB as the threshold of noise compatibility with residential land uses, this study contains additional data in response to the May 7, 1999 EOEA Certificate which requested Massport to extend the outer limits of its DNL and population analyses to the 60 dB DNL contour. Additionally, since there are adverse impacts foreseen within the 65 dB DNL noise contour area, FAA procedures call for a general characterization of land uses within the 60 dB DNL contour area.

Logan Airport's noise contours are produced using an FAA-approved computer program known as the Integrated Noise Model, or INM. The INM requires detailed operational information including factors such as:

- The physical runway configuration, the numbers and types of aircraft using the airport,
- Whether the flights occur during the day or night, and
- How often they use each runway, and which flight paths they follow.

Each of these affects the noise exposure in surrounding neighborhoods. (See Section 5.2 for a more detailed discussion of the noise analysis.) The geographic area of the 60 dB DNL or greater contours changes depending on the year's activity and the operational scenarios being evaluated, but it generally includes the communities of Boston (including downtown Boston, East Boston, South Boston, Dorchester, Roxbury, and the South End), Winthrop, Chelsea, Revere, and Everett.

5.1.1.2 Logan Airfield Study Area

The boundaries of the Airfield study area are shown in Figure 5.1-2. The study area encompasses all airport taxiways and runways as well as the South Cargo Area. Also shown for locational context are nearby airport facilities such as passenger terminals, cargo handling areas, and other facilities. Additional descriptions of the airfield site characteristics are provided in Section 5.5 – Biotic Communities and 5.7 - Soils/Sediment Characterization.

5.1.1.3 Base Year Analysis

This Supplemental DEIS/FEIR includes updated operational and environmental analyses of 1998 conditions consistent with those contained in the *Logan Airport 1998 Annual Update.*[6] While the *Logan Airport 1999 Environmental Status and Planning Report*[7] published in December 2000 includes updated analyses for 1999, the differences between the two study years are small. Between 1998 and 1999, operations declined by 2.5 percent, primarily due to a decline in regional carrier operations.[8] The fleet mix and runway use varied little, the shape of the noise contours and the population impacts, and the air quality and other environmental analyses also yielded similar results.[9] Since the relevant comparison for evaluating the proposed Airside Project improvements is the comparison between the No Action and Preferred Alternatives, and since 1998 and 1999 are similar in terms of passengers, operations, and environmental impacts, this Supplemental DEIS/FEIR uses the 1998 modeling analysis as a representation of recent conditions at Logan.

5.2 Noise

Chapter 5 of the Airside Project Draft EIS/EIR presented a detailed assessment of the noise-affected environment around Logan using 1993 as the study year. Both flight and ground operations were modeled in detail and exposures were described using a variety of noise metrics. Chapter 5 of this Supplemental DEIS/FEIR introduces 1998 to describe the affected environment. This new scenario serves to update the Airside Project Draft EIS/EIR by presenting actual noise exposure data for 1998. The information is taken primarily from the *Logan Airport 1998 Annual Update,* a document published annually by Massport in compliance with requirements of the Massachusetts Environmental Policy Act.

7 *Logan Airport 1999 Environmental Status and Planning Report*, December 15, 2000.
8 A more detailed comparison of the change between 1998 and 1999 passengers and operations is included in Chapter 2 of the ESPR.
9 The ESPR compares all of the 1998 and 1999 analyses and discusses the differences in detail.

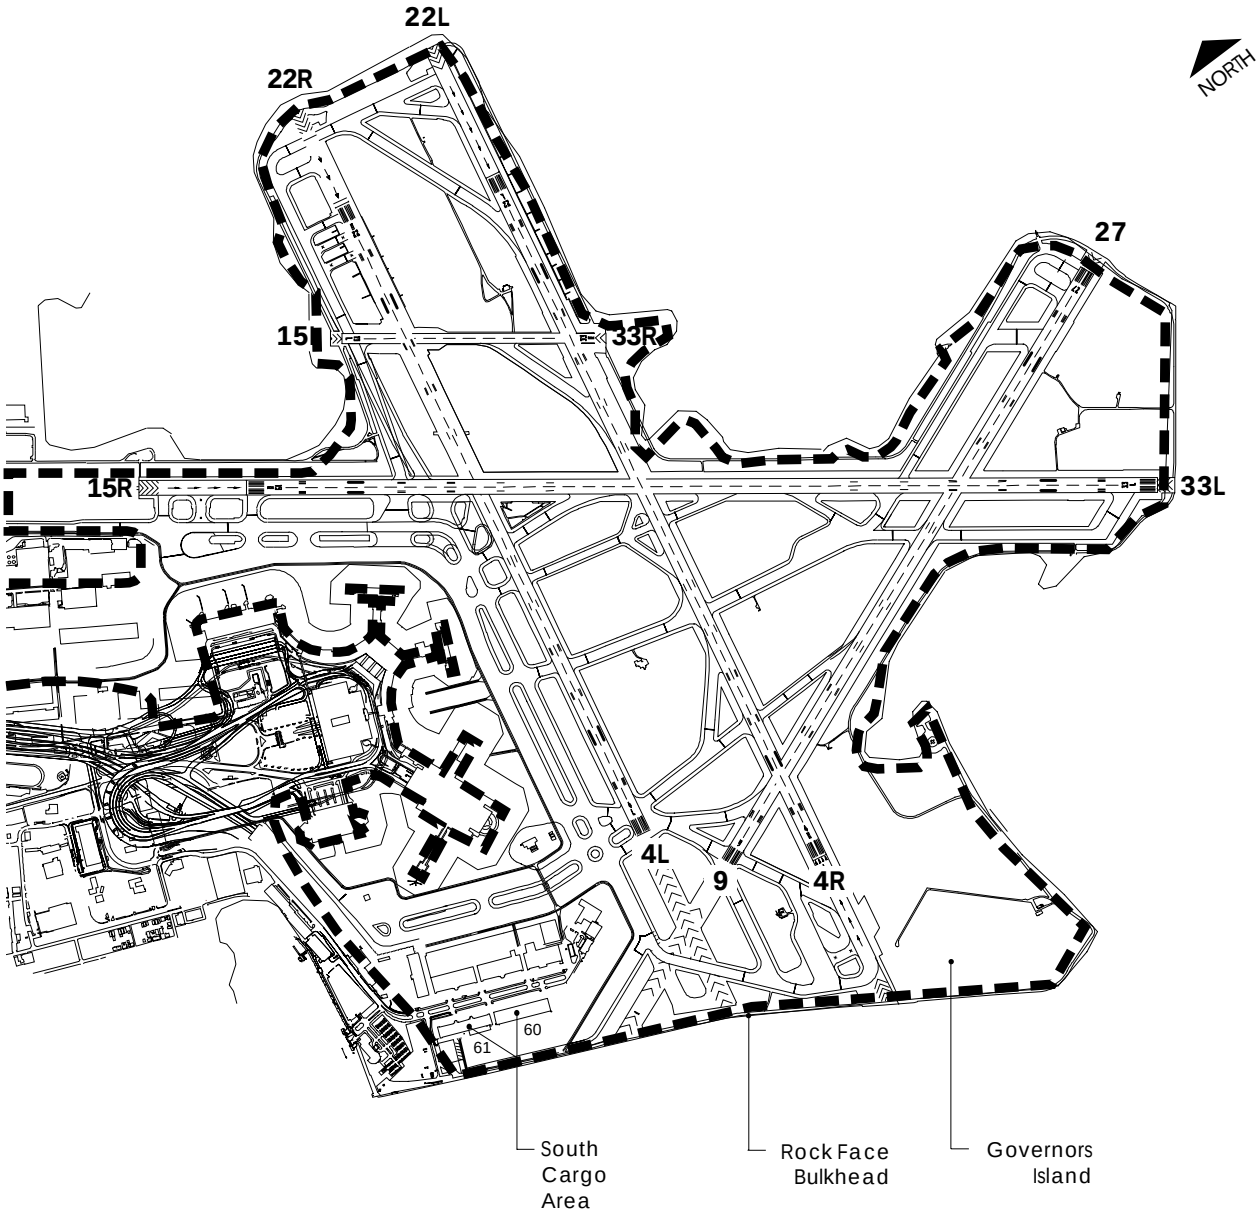

Figure 5.1-2
Airfield Study Area

7466-FIG-5.1-2.p65

This Supplemental DEIS/FEIR includes updated operational and environmental analyses of 1998 conditions similar to that contained in the Logan Airport *1998 Annual Update* prepared in October 1999. While the *1999 Environmental Status and Planning Report* published in December 2000 includes updated analyses for 1999, the differences between the two study years are small. Between 1998 and 1999, operations declined by 2.5 percent, primarily due to a decline in regional carrier operations.[10] Since the fleet mix and runway use varied little, the shape of the noise contours and the population impacts were also similar, with slightly less impact in Winthrop and Boston and slightly more impact in Chelsea and Revere in 1999 compared to 1998.[11] The air quality and other environmental analyses also yielded similar results.[12] Since 1998 and 1999 are similar in terms of passengers, operations, and environmental impacts, this Supplemental DEIS/FEIR includes the 1998 modeling analysis as a representation of recent conditions at Logan.

Later in this Supplemental DEIS/FEIR, Chapter 6 presents an assessment of the noise impacts of the Preferred Alternative under two future fleet assumptions and compares those results to the No Action Alternative, as well as to 1998.

5.2.1 Noise Metrics

Both the Airside Project Draft EIS/EIR and this Supplemental DEIS/FEIR depend heavily on the reader's comprehension of common metrics used to evaluate aircraft noise. The two most pertinent to this document are (a) the DNL, and (b) times above designated "threshold" sound levels, commonly referred to as "Time-Above", or TA. Appendix E of this Supplemental DEIS/FEIR provides a summary of noise metrics. The reader is urged to become familiar with the terminology and related background material in order to maximize understanding of the more condensed material presented here.

5.2.2 Modeling Noise of Flight Operations

The following section outlines the FAA's noise modeling tools and their application at Logan.

5.2.2.1 FAA's Integrated Noise Model

The basic tool used to model aircraft flight operations is the Integrated Noise Model, or INM. Developed by the FAA and prescribed on Federally-sponsored projects such as the Airside Project, the INM utilizes airport geometry, descriptions of aircraft operations, and an internal database of noise and performance characteristics to compute the noise of individual flights, adds them together depending on the noise

▼

10 A more detailed comparison of the change between 1998 and 1999 passengers and operations is included in Chapter 2 of the *1999 ESPR*.

11 A more detailed comparison of the change between 1998 and 1999 noise impacts is included in Chapter 6 of the *1999 ESPR*.

12 The *1999 ESPR* compares all of the 1998 and 1999 analyses and discusses the differences in detail.

metrics of interest, and presents the accumulation as a set of contours and/or noise calculations at specific points.

Detailed operational inputs to the INM fall generally into three categories of information including:

- Daily numbers of daytime and nighttime takeoffs and landings by specific aircraft types,
- Typical flight path and runway geometry, and
- Average statistics on usage of each runway and flight path by various aircraft groups.

Historical data from sources such as Massport's noise monitoring system, which records and saves FAA radar data from Logan's Air Traffic Control Tower, are used to develop descriptions of past noise environments. Predicted aspects of an airport's operations are used to evaluate alternative assumptions regarding growth, future aircraft fleets, shifting of flight paths, new runway and taxiway configurations, delay, noise mitigation measures, and other critical planning efforts.

INM users do not normally alter the model's internal noise and performance databases as a part of the modeling process. However, when there is an identifiable need, the FAA requires that any changes to these databases be approved by them prior to use on any FAA-related project. Database adjustments have been made for the Airside Project. In 1996, Massport applied for and received permission to make adjustments to the INM to better account for Logan's unique location surrounded on nearly all sides by water. The water's surface affects propagation of sound into shorefront neighborhoods and is not normally accounted for in the standard INM algorithms. The FAA-approved adjustments are described briefly in the section that follows. (See Appendix E of this document for the FAA's written authorization to modify the INM model.)

5.2.2.2 INM Version 5.0 Upgrade and Adjustment

In 1995, a comparison of INM Version 5.0 modeled noise results with the measured noise levels obtained from Massport's extensive noise monitoring system indicated that the model accurately predicted the noise from aircraft in flight during takeoff but under-predicted the noise from takeoff ground roll and the approach noise just before landing. Therefore, adjustments to the model were developed for arrival noise below 1,000 feet altitude and for the noise radiated from the aircraft during the ground-roll portion of the takeoff.

Authorization for use of the adjustments at Logan was issued in May 1996 by FAA's Office of Environment and Energy. Subsequent noise analyses have been conducted with the adjustments (See Appendix E). In particular, the Airside Project Draft EIS/EIR and this Supplemental DEIS/FEIR, as well as the *Logan Airport 1994/95 Generic Environmental Impact Report* (GEIR) and the *1996, 1997,* and *1998 Annual*

Updates, used INM Version 5.0 with the authorized adjustments for their respective noise analyses.

5.2.3 Model Inputs for INM Noise Analyses

Many of the operational inputs used to model noise exposure for 1993 are summarized in Sections 5.2.6, 6.2.1, and Appendix H of the Airside Project Draft EIS/EIR. This section of the Supplemental DEIS/FEIR updates the Airside Project Draft EIS/EIR by summarizing the operations used to model the 1998 exposure levels and draws brief comparisons between the two periods.

5.2.3.1 Fleet Mix and Operations

For purposes of computing 24-hour DNL's, annual aircraft operations at Logan are subdivided into average daily operations by specific aircraft types, and in some cases by engine model as well. Massport's Noise Office compiles these records of commercial jet and turboprop activity from a variety of sources including published schedules in the Official Airline Guide, comprehensive reports provided by carriers and cargo operators as part of their compliance with Massport's Noise Rules, and reports from the two main flight service companies operating at Logan. The data are consolidated into average daily takeoffs and landings for daytime hours (7:00 AM to 10:00 PM) and nighttime hours (10:00 PM to 7:00 AM) – the periods used in DNL calculations – and are sorted into different trip lengths used by the INM to approximate takeoff weights. Radar data are used to determine actual, rather than scheduled arrival and departure times. General aviation operations, were formerly excluded from modeling because of the difficulty identifying aircraft types and because they made only a minor contribution to total traffic at Logan. The operations have been approximated in the Airside Project analyses and are included in the 1998 analyses which use FAA radar data to determine the numbers and times of operations by these specific aircraft types.

Table 5.2-1 summarizes the average daily operations at Logan for 1998. Commercial jet operations are classified by their noise certification level. Noisier "Stage 2" aircraft (such as the older Boeing 727s and 737s, and McDonnell-Douglas DC-9s) meet initial Federal Aviation Regulation (FAR) Part 36 noise limits issued in 1969, but not the more stringent "Stage 3" limits applicable to newer aircraft (such as the Boeing 737-300 and 737-400, the Boeing 757 and 767, McDonnell-Douglas MD-80s, and Airbus A-300s and A-320s). The Stage 3 operations summary includes Stage 2 aircraft that have been retrofitted with hushkits or new engines to meet the Stage 3 criteria. The number of Stage 3 aircraft has increased steadily based on the ongoing replacement of Stage 2 operations by Stage 3 aircraft in the Logan fleet mix. In 1993, 69 percent of the commercial jet operations at Logan were in Stage 3 aircraft; in 1998, that percentage increased to 87 percent. The 87 percent also compares favorably to the 1998 national average of 82 percent, due in large measure to the benefits of Massport's Noise Rules that have resulted in conversion to Stage 3 aircraft faster than federal regulations.

As of January 1, 2000, operators of large jet aircraft (weighing over 75,000 pounds) are required by *The Airport Noise and Capacity Act of 1990* to have 100 percent of their fleets compliant with Part 36 Stage 3 noise limits. The *Logan Airport 1998 Annual Update* estimated the benefit of an all Stage 3 fleet to be on the order of 3 dB.

Table 5.2-1
1998 Modeled Daily Operations

1998 Operations	Stage 2 Jets	Stage 3 Jets	Turboprops	Totals		
	Day/Night	Day/Night	Day/Night	Day	Night	Daily
Commercial	85/6	541/96	553/22	1,179	124	1,303
General Aviation	5/0	31/4	37/16	73	20	93
Total	90/6	572/100	590/38	1,252	144	1,396

Note: "Day" defined as 7:00 AM to 10:00 PM and "Night" defined as 10:00 PM to 7:00 AM, consistent with the definitions used in DNL calculations.

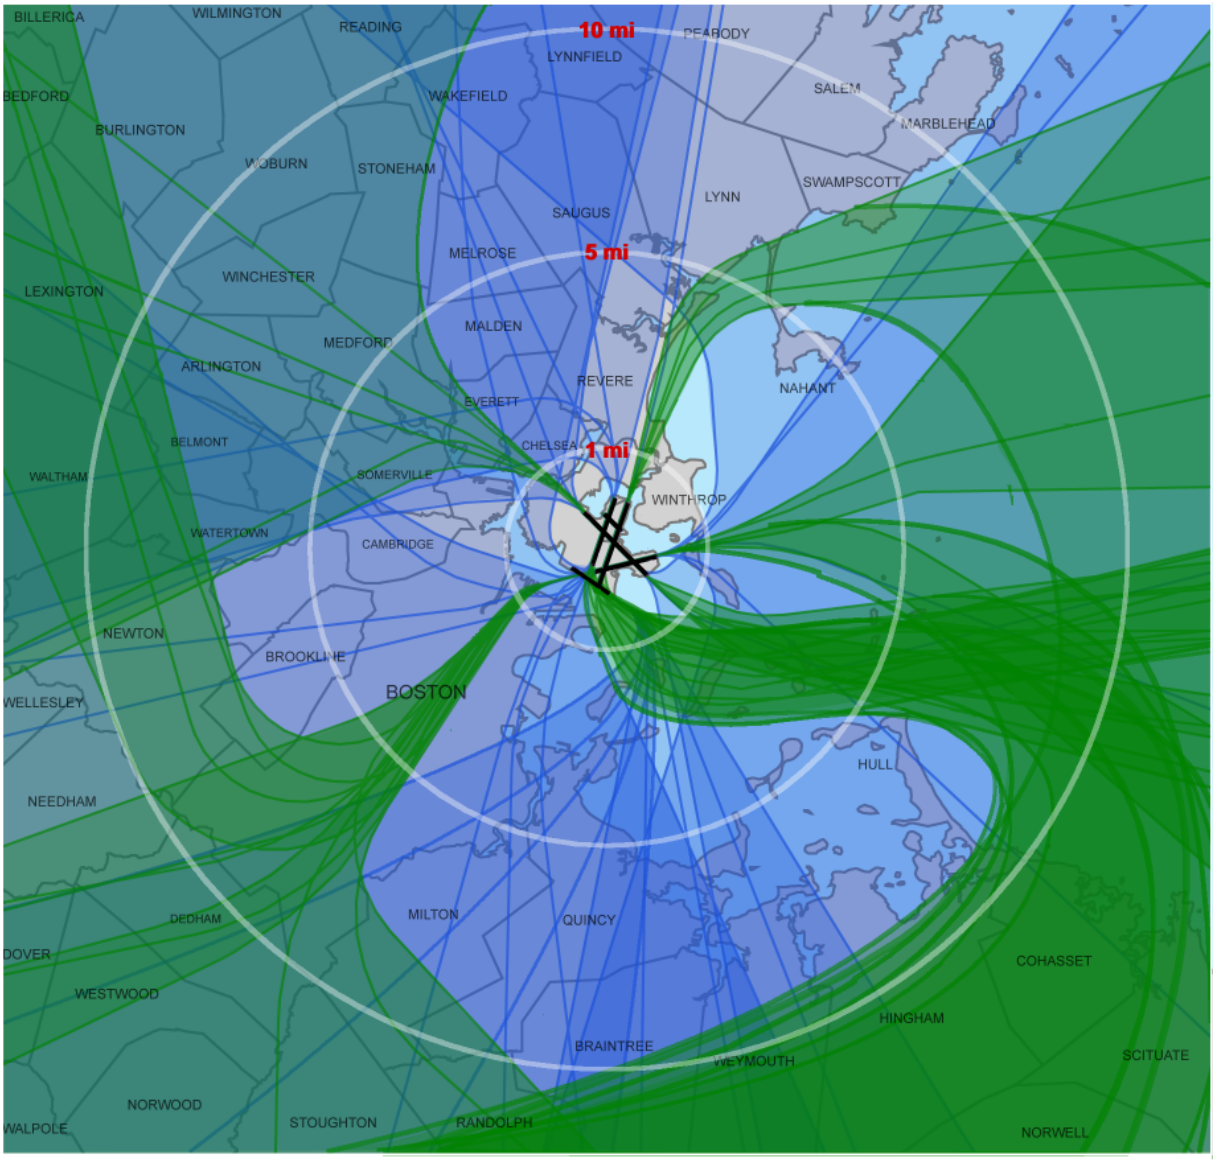
5.2.3.2 Flight Tracks

The flight tracks used in the INM are derived from radar tracks obtained by the Noise Abatement Office at Massport from the FAA's Automatic Radar Terminal System-3 (ARTS) radar at Logan. This radar system obtains the location of each aircraft in the terminal airspace area at intervals of 4 seconds. Massport software is designed to determine the actual tracks and profiles of individual aircraft and to develop tracks for modeling purposes. For example, jet departure operations are typically modeled by a set of five to as many as 15 tracks per runway, while a separate set of three to five tracks per runway is used to model turboprop activity.

The resulting sets of model tracks represent an approximation of the flight corridors that are actually overflown during a year by operations from and to each of the runways. Figure 5.2-1 shows the existing jet and turboprop departure flight tracks. Figure 5.2-2 shows the existing jet and turboprop arrival flight tracks for all runways.

With one exception, the 1998 case uses the same tracks as have been used in each of the scenarios that do not include the new Runway 14/32. The one difference pertains to the departure corridor off Runway 27. For both the Airside Project Draft EIS/EIR and this Supplemental DEIS/FEIR, modeled tracks were developed based on objectives set forth in the FAA's Record of Decision (ROD)[13] on the Environmental Impact Statement for the new Runway 27 departure procedure. The procedure, itself, had not been implemented at the time these Airside Project analyses were initiated so the track locations had to be estimated. Since that time, the tracks and their usage were based on actual radar data for 1998.

[13] Runway 27 Final Environmental Impact Statement, 1997.



Jet Departures in Green **Turboprop Departures in Blue**

Aircraft Altitude Along the Flight Path (from runway departure)

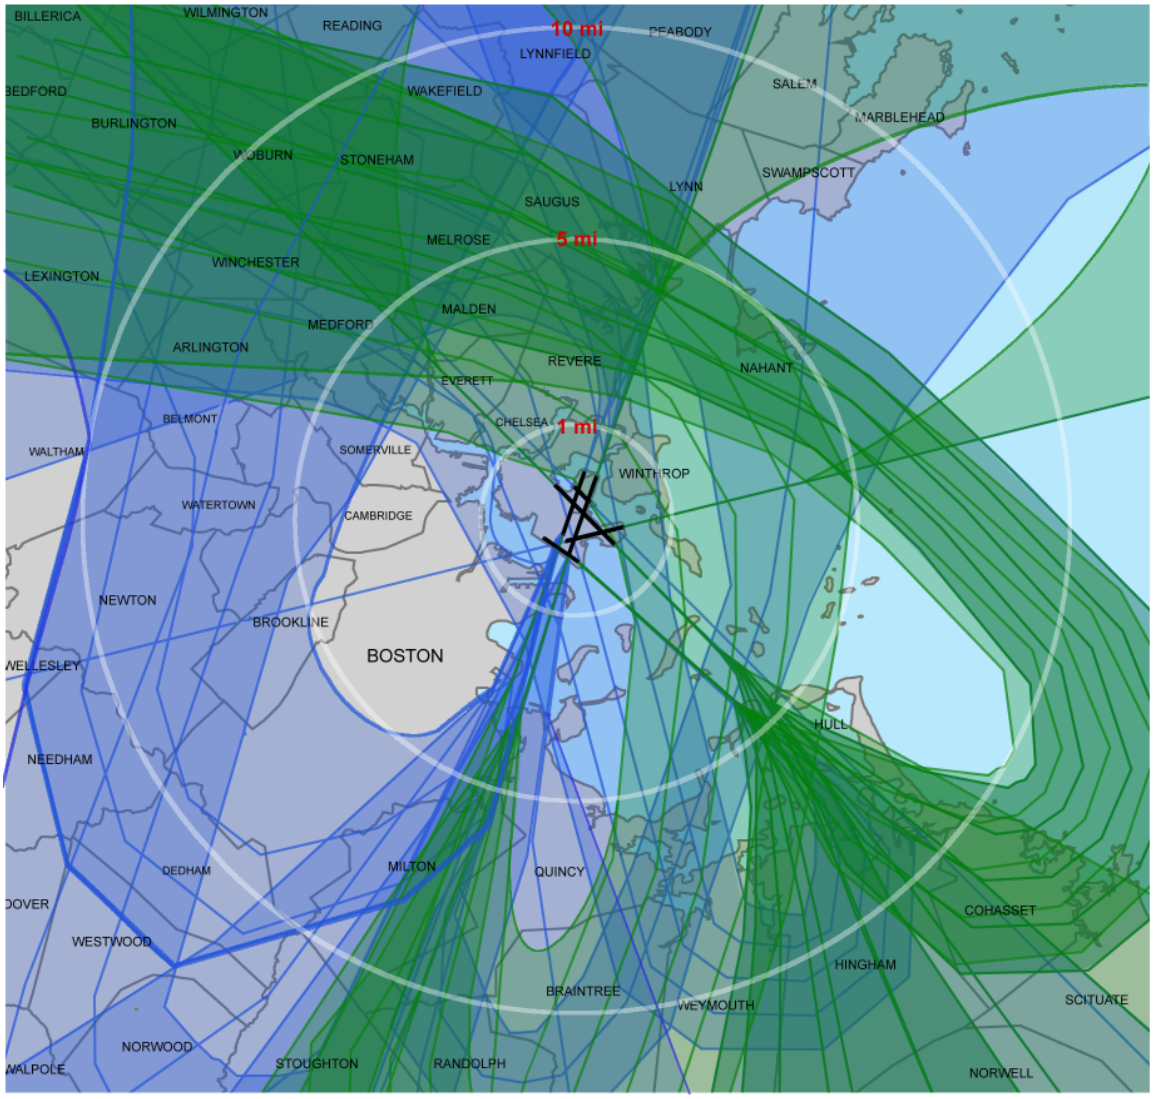
1 Mile from Takeoff= 1,000 ft. or Less 5 Miles from Takeoff = 2,000 ft. or More 10 Miles from Takeoff = 4,000 ft. or More

Notes: Mileage rings are for reference only and do not indicate actual distance along the flight path
Jet departures cross the shoreline of the Southshore at or above 6,000 ft.

Figure 5.2-1

Modeled Departure Flight Tracks for Existing Runway Configurations

7466-FIG-5.2-1.p65



Jet Arrivals in Green **Turboprop Arrivals in Blue**

Aircraft Altitude Along the Flight Path (from runway touchdown)

1 Mile from Touchdown = 500 ft. or Less 5 Miles from Touchdown = 2,000 ft. or Less 10 Miles from Touchdown = 3,000 ft. or Less

Notes: Mileage rings are for reference only and do not indicate actual distance along the flight path
All jet arrivals descend from 11,000 ft. to 6,000 ft. entering final approaching airspace

Figure 5.2-2
Modeled Arrival Flight Tracks for Existing Runway Configurations

7466-FIG-5.2-2.p65

The first full year that the new departure procedure for Runway 27 was in effect was 1997. Analyses performed by Massport and reported on in the *1997 Annual Update* indicated that the flight corridor was not being maintained by the percentage of aircraft required by the FAA's ROD. This resulted in an increase in population impacts within the 65 dB DNL contour for 1997. Data collected and analyzed by Massport for the *1998 Annual Update* indicate that the aircraft pilots have been making progress towards attainment of the required flight corridor objectives, but the requirements are still are not being fully met. Thus, differences continue to exist between the 1998 flight tracks and those in the Airside Project EIS/EIR analyses which assumes full achievement of the ROD directives. Full achievement of the ROD tracks was estimated in the *1998 Annual Update* to reduce the number of residents of South Boston exposed to noise above 65 dB DNL by about 2,700 people. The FAA will continue to encourage and monitor compliance with the ROD departure tracks with the intention of further realizing these benefits.

5.2.3.3 Runway Use

Runway use refers to the frequency with which aircraft utilize each runway during the course of a year, as dictated or permitted by wind, weather, aircraft weight, air traffic control conditions, and noise considerations. The more often a runway is used throughout the year, the more noise is created in communities located off the ends of that runway.

Runway use statistics for 1998 are based on traffic counts from radar data processed by Massport's noise and operations monitoring system. Takeoffs and landings are counted separately and sorted into daytime and nighttime operations, then further separated by groups of aircraft having different performance characteristics (for example turboprops separately from 747's) reflecting existing runway use restrictions and takeoff length requirements for certain aircraft. A summary of the computed usages by all jet aircraft was previously published in the *Logan Airport 1998 Annual Update* ; it is reproduced here as Table 5.2-2. Also included are 1998's effective runway utilizations statistics (where usage at night is weighted by a factor of ten). These, too, were reported in the *1998 Annual Update* and are computed each year to compare with Preferential Runway Advisory System[14] (PRAS) goals. The goals, themselves, are discussed in detail in Chapter 4 and their implications on noise exposure are discussed in Chapter 6.

[14] The PRAS program is based on an FAA initiative, with the objective of reducing noise exposure for the most highly impacted communities. At Logan, PRAS is a computer program that recommends to the FAA air traffic controllers, runway configuration options that will meet weather and demand requirements, while providing an equitable distribution of the airport's noise impacts on the surrounding communities. The primary objectives of PRAS are to distribute the noise in accordance with annual runway utilization goals, and to provide short-term relief from continuous operations over the same neighborhoods at the ends of the runways. PRAS goals for Logan were established by a PRAS Advisory Committee (including representatives from Massport, the FAA and neighboring communities). PRAS was first implemented in 1983, and the program has undergone two major enhancements since then.

5.2.4 1998 Noise Exposure Levels

Section 5.2.7 of the Airside Project Draft EIS/EIR presented noise exposure levels from flight activity as well as from ground taxi activity using the operations data developed for the 1993 modeled scenario. This current section of the Supplemental DEIS/FEIR updates the analysis of noise from flight operations by presenting the 1998 case.

Table 5.2-2
1998 Actual and Effective Runway Utilizations for Jet Aircraft

	1998 Actual Usage		1998 Effective Usage	
Runway	Arrivals	Departures	Arrivals	Departures
4L	2%	0%	36.7%*	0.0%
4R	41%	8%		6.6%
9	0%	35%	0.0%	29.9%
15R	2%	6%	1.2%	10.9%
22L	7%	5%	11.9%	30.9%*
22R	0%	28%	0.0%	
27	28%	14%	21.7%	16.6%
33L	19%	5%	28.6%	5.2%
Total	100%	100%	100.1%	100.1%

Note: Small addition errors may exist within the table due to rounding.
* For closely-spaced parallel runways, Massport computes effective usage for the combined pair except when use restrictions permit activity to only one of the parallels.

5.2.4.1 Noise from Flight Operations

24-Hour Day-Night Sound Levels (DNL)

For 1998 actual operations, 60, 65 and 70 dB DNL contours generated by the INM are presented in Figure 5.2-3. DNL noise exposure contours are a graphical representation of how the cumulative noise from Logan's aircraft operations is distributed over the surrounding area on an average day of a given year. Comparing DNL contours from different years or different forecast scenarios provides valuable information for noise abatement programs or proposed airport development projects.

Both the Department of Housing and Urban Development (HUD) and the FAA define 65 dB DNL as the threshold of noise incompatibility with residential land uses. Thus, the 65 dB DNL contour is important for population impact assessments. In addition, this study contains data in response to the May 7, 1999 EOEA Certificate which requested Massport to include the 60 dB DNL contour.

The INM produces population estimates simultaneously with the development of DNL contours. Estimates of the numbers of people residing within each noise exposure contour are summarized in Table 5.2-3.

Quincy	0	0	0	0
Revere	5,300	3,168	0	0
South Boston	22,511	3,553	48	0
Winthrop	15,120	8,613	2,041	519
Totals	**93,358**	**23,296**	**2,679**	**577**

1 Portions of Dorchester, Roxbury, and the South End are included in the Boston totals.
Source: *1998 Annual Update*.

The 1998 population counts shown above and presented first in the *Logan Airport 1998 Annual Update* are based on the same 1990 federal census as used for the Airside Project. Thus, both the contours in Figure 5.2-3 and the population counts within the contours indicate significant differences in the degree of impact occurring within individual communities. Winthrop and East Boston are most affected, with significant numbers of residents experiencing noise greater than 70 dB DNL, and some experiencing it at levels above 75 dB DNL. South Boston and Revere are generally next most affected. Exposures at the highest noise levels support the continuing need to improve compliance with PRAS goals.

Noise Levels at Specific Monitoring Locations

Massport maintains a state-of-the-art noise monitoring system that continuously records noise levels at each of its permanent noise monitor locations. At present, there are 29 installed and operational noise monitors in residential neighborhoods recording noise from flight operations at Logan.

For the Airside Project noise analyses, 21 of these sites, plus 2 additional locations (A and E) were selected for detailed location-specific analysis (see Figure 5.2-4). These selected monitoring locations included all of the highest noise level measurement sites close to the airport, as well as those further from the airport that are consistently overflown. Five sites were not included since they did not meet one of these criteria. Their measurements were expected to contain enough noise of local origin such that their correlation with modeled aircraft noise would be low. The remaining three sites had not yet been installed at the time the Airside Study was initiated. Locations A and E were added for analysis of noise from ground operations and were discussed in detail in the Airside Project Draft EIS/EIR.
At each of these 23 specific locations, a number of noise computations were completed and reported in the Airside Project Draft EIS/EIR. These included:

- Day-Night Sound Level (DNL)
- Maximum Sound Level (Lmax)
- Night (10:00 PM to 7:00 AM) Equivalent Sound Level (LeqN)
- Times Above Sound Levels of 55, 65, 75, 85, and 95 dB at night (TAN)
- Times Above Sound Levels of 55, 65, 75, 85, and 95 dB for 24-hour days (TA24)

In this Chapter of the Supplemental DEIS/FEIR, similar data for 1998 are reported where available. Table 5.2-4 summarizes the DNL calculations from the INM at the 21 noise monitoring locations used in the Airside analysis. It also includes the times above 65, 75, and 85 dB thresholds for nighttime hours (TAN) and for average 24-hour periods (TA24) at the same 21 locations. These data were reported initially in Table 5-9 of the *1998 Annual Update*. The threshold levels of 65, 75, and 85 dB were identified in the 1998 *Annual Update* as covering different degrees of speech interference depending on factors such as whether people are outdoors, or indoors with windows open or closed.

Observations regarding TA calculations for 1998 are similar to those for DNL. The highest exposure levels occur at Sites 4 and 7 at Bayview and Grandview in Winthrop and along Loring Road in Winthrop, where DNL values are 79 and 76 dB, respectively. These same locations experience sound levels exceeding 85 dB for about 21 to 23 minutes per day and experience daily levels above 75 dB for almost an hour at Site 4 to nearly an hour and a half at Site 7. Sites 9 and 12 at Bayswater near Annavoy in East Boston and at the East Boston Yacht Club also experience high exposures. Their DNL levels are 72 and 74 dB, respectively, and they are exposed to sound levels above 85 dB for 8 and 16 minutes per day. In fact, the five most highly exposed sites, both at night and over 24 hours, are located in Winthrop and East Boston – the same communities identified earlier as having high numbers of people residing in areas where the DNL exceeds 70 dB. Again, these analyses indicate a need for improved conformance with PRAS goals if these highest exposures are to be reduced. Chapter 6 addresses the changes that occur in these communities under the Preferred Alternative as air traffic controllers are better able to achieve the goals.

N/A Not available.

5.2.4.2 Ground Taxi Noise Levels

The Airside Project Draft EIS/EIR provided a detailed analysis of noise from aircraft on taxiways using modeled 1993 operations. Calculations were made for the same five metrics as were assessed for 1993 flight operations:

- Day-Night Sound Level (DNL)
- Maximum Sound Level (Lmax)
- Night (10:00 PM to 7:00 AM) Equivalent Sound Level (LeqN)
- Times above sound levels of 55, 65, 75, 85, and 95 dB at night (TAN)
- Times above sound levels of 55, 65, 75, 85, and 95 dB over 24 hours (TA24)

Chapter 6 of this Supplemental DEIS/FEIR summarizes the analysis of ground noise that was conducted for the Airside Project Draft EIS/EIR, comparing the No Action and Preferred Alternative. Readers interested in further analyses of ground noise are referred back to the Airside Project Draft EIS/EIR.

5.2.5 Comparing Measured and Modeled Noise Levels

Massport's permanent noise monitoring system continuously measures the noise levels at each of 29 microphone locations around the airport. Twenty-one of those sites were operational and used in the analysis of the Airside Improvements Planning Project, as shown earlier in Figure 5.2-1. During normal operation, noise monitors at the microphone locations measure hourly noise exposure levels as well as a variety of metrics associated with individual noise events that exceed preset threshold sound levels. These data are transmitted back to Massport's Noise Abatement Office where daily DNL values as well as other noise metrics are computed from the measured data and summarized.

In past years, *Logan Airport GEIRs* and *Annual Updates* have compared the annual average day values of DNL as measured by Logan Airport's monitoring system to INM-computed annual average values of DNL. Though many of the results are consistent, several have indicated significant differences of 10 or more decibels. One of the major factors contributing to these differences has been that the measured levels include community-based noise sources in the vicinity of the monitor, while the INM-computed levels include the noise only from aircraft. This, in addition to aircraft, has tended to make measured levels higher than predicted values at certain locations.

As a result, commencing at the end of 1997, Massport enhanced its monitoring system to separate aircraft noise events from other sources and produce "aircraft-only" DNL values in addition to the total DNL values it has previously reported. Table 5.2-5 presents these measurement results for 1999 and compares them to INM-generated levels for 1999.

Among the more significant observations regarding these data are the following:

- The average difference in 1998 between the *aircraft-only* DNLs and the INM-generated values at all 29 monitoring locations is approximately 0.9 dB (measured values averaging higher than computed). In 1998, this difference in aircraft-only DNLs was 1.5 dB (measured values also averaging higher than computed).

- At monitoring sites in higher noise environments where measurements are greater than 60 dB (and where it would be expected that the measured levels are more easily identified as aircraft), the average difference between *aircraft-only* DNLs and INM-generated levels in 1998 is 0.2 dB (measured values averaging higher than computed). In 1998, this difference was 0.4 dB.

For a second year, these measured results show high correlation with INM calculations and indicate major improvement in the monitoring system's capabilities. The close agreement that these new aircraft-only levels have with INM-generated values of exposure significantly enhances the monitoring system's value as an analytical tool and also fully corroborates the INM's noise prediction capability.

Table 5.2-5
Comparison of Measured DNL Values to INM-computed DNL Values for 1998

5.3 Cultural Resources

This section summarizes relevant regulations and provides a description of historic properties within the project study area. An historic property, as defined by Section 106 of the National Historic Preservation Act, is any prehistoric or historic district, site, building, structure, or object, included in, or eligible for inclusion in, the National Register of Historic Places (36 CFR 800.16). Section 4(f) of the Department of Transportation Act references "historic sites." Both historic properties and historic sites refer to National Register eligible or listed properties.

5.3.1 Regulatory Context

Cultural resources, which include parklands and historic resources, are regulated under Section 4(f) of the Department of Transportation Act, the National Historic Preservation Act ("Section 106"), and by state regulations concerning historic properties.

5.3.1.1 Section 4(f) of the Department of Transportation Act

Section 4(f) of the Department of Transportation Act of 1966 (recodified as 303(c) of 49 USC) ,as amended, directs that the Secretary of Transportation shall not approve any program which requires the use of a significant publicly owned public park, recreation area, or wildlife and waterfowl refuge, or any significant historic site, unless there is no feasible and prudent alternative and the harm resulting from the use is minimized.

The potential use of a Section 4(f) property may be either direct or indirect. Direct use is typically considered to include physical involvement of a site, including property acquisition, or facilities modification or relocation. Indirect impacts include changes in access, visual impacts, increased noise levels, and other similar conditions. According to FAA Order 5050.4A:

> *"when there is no physical taking, but there is the possibility of use or of adverse indirect impacts to Section 4(f) land, the FAA must determine if the activity associated with the proposal conflicts with, or is compatible with the normal activity associated with this land. The proposed activity is compatible if it would not affect the normal activity or aesthetic value of a public park, recreation area, refuge, or historic site. When Section 4(f) applies and agencies which have jurisdiction agree that the effects of the action will be satisfactorily mitigated, the action may be considered not to have significant Section 4(f) impacts, and no further analysis is needed."*

5.3.1.2 Section 106 of the National Historic Preservation Act of 1966

The National Historic Preservation Act of 1966, as amended (NHPA), established the Advisory Council on Historic Preservation (ACHP) to advise the President and

Congress on historic preservation matters, to recommend measures to coordinate federal historic preservation activities, and to comment on federal actions affecting properties included in or eligible for inclusion in the National Register of Historic Places. Under Section 106 of the NHPA, federal agencies are responsible for identifying National Register listed or eligible properties and sites and for assessing the effects of agencies' actions on them. The procedures prescribed in Section 106 are referred to as the "Section 106 process" and are set forth in regulations issued by the ACHP, "Protection of Historic Properties" (36 CFR 800). The ACHP regulations emphasize consultation among the responsible federal agency (in this case the FAA, and / or its designee, Massport), the Massachusetts State Historic Preservation Office (MASHPO) / Massachusetts Historical Commission (MHC), and other interested parties. The Section 106 process is being undertaken for the Logan Airside project and the FAA / Massport have consulted with the MASHPO / MHC.

5.3.1.3 Protection of Properties Included in the State Register of Historic Places

The proposed project is also subject to review by the MHC under the Massachusetts General Laws, Chapter 9, Sections 26-27C as amended by Chapter 254 of the Acts of 1988 and the implementing regulations, 950 CMR 71. This state law covers actions of Massachusetts agencies and involves a state process in addition to the federal process under Section 106 of the ACHP, which governs the actions of federal agencies. Standards for the state and federal review processes are similar, with the exception that properties subject to review under Chapter 254 are those listed in the State Register of Historic Places. Section 106 and Chapter 254 reviews are carried out simultaneously by the MASHPO / MHC.

5.3.2 Cultural Resources Context

The Preferred Alternative has the potential to increase noise-exposed populations. A review of MHC files, including the National Register of Historic Places and the Inventory of Historic and Archaeological Assets of the Commonwealth, and field survey were undertaken to identify historic resources within the project area and in surrounding communities.

5.3.2.1 Section 106 Resources

A review of MHC files, including the National Register of Historic Places and the Inventory of Historic and Archaeological Assets of the Commonwealth, and field survey were also undertaken to identify historic resources regulated under Section 106 within the project area and in surrounding communities. Refer to Figure 5.3-1 showing the 1998 65 dB DNL contour on a map of parklands.

5.3.2.2 Other Section 4(f) Resources

In response to the May 7, 1999 EOEA Scope , specific parklands have been identified for analysis, namely the Boston Harbor Islands, Arnold Arboretum, Franklin Park, and the Emerald Necklace. These resources are described below (see Figure 5.3-1).

Boston Harbor Islands

In November 1996, the Boston Harbor Islands became a national park area under the supervision of the National Park Service. The Boston Harbor Islands National Recreation Area recognizes that the islands and the shoreline beaches and access points are one natural and cultural resource system. As a National Recreation Area, the park preserves and protects the open spaces and natural and cultural features of the harbor islands.

According to the legislation that established the Boston Harbor Islands Recreational Area:

> "*the present and future maintenance, operation, improvement, and use of Boston-Logan International Airport and associated flight patterns from time to time in effect shall not be deemed to constitute the use of publicly owned land or a public park, recreation area, or other resource within meaning of section 303(c) of title 49, United States Code, and shall not be deemed to have a significant effect on natural, scenic, and recreation assets with the meaning of section 47101(h)(2) of title 49, United States Code.*"[15]

Therefore, Boston Harbor's National Recreation Area is considered to be a compatible land use.

Part of Massachusetts Bay, Boston Harbor, touches six of Boston's neighborhoods (East Boston, Charlestown, Downtown, Fort Point, South Boston, and Dorchester) and seven other municipalities (Hull, Hingham, Weymouth, Quincy, Chelsea, Revere, and Winthrop). Linking the inner and outer harbor are more than thirty islands that range in size from less than one acre to 214 acres that together total 1,200 acres.

[15] Sec. 1029. Boston Harbor Island Recreation Area. Excerpted from P.L. 104-333, 110 Stat. 4093 the "Omnibus Public Lands Management Act of 1996."

Arnold Arboretum

Arnold Arboretum located in the Jamaica Plain section of Boston is recognized as the pre-eminent institution in the United States for the study of ligneous (woody) plants. Established in 1872 through a bequest from the estate of James Arnold, the Arboretum has since more than doubled in size and has assembled a collection of over 6,000 varieties of trees and shrubs from all over the Northern Temperate Zone. The Arboretum is listed on the National Register of Historic Places and is a National Historic Landmark.

Olmsted Park System including the Emerald Necklace and Franklin Park

The comprehensive park system, which Frederick Law Olmsted Sr. planned for the City of Boston in the late 1870s, is one of the nation's outstanding examples of a multi-use open space. Olmsted's original plan for the park system had three purposes: to create a much needed municipal open space while solving an engineering problem; to link annexed parts of the city with its historic center; and to provide a variety of forms of recreation. The Emerald Necklace includes a series of parks linked by continuous parkways. It curves from the mouth of the Muddy River to Franklin Park. The terminus of the system is at Franklin Park, one of Olmsted's masterpieces. In 1885, Olmsted designed this large rural park especially for working class people. The park, included in the earliest schemes for Boston's park system was financed in part by a bequest made to the City by Benjamin Franklin. The Emerald Necklace parks, including Franklin Park, are contributing elements to a National Register of Historic Places historic district and are a Boston City Landmark.

5.4 Air Quality/Odors

This section contains a general discussion of current air quality conditions in the vicinity of Logan and an overview of regulatory criteria. Specifically, this material includes:

- A summary of historic and current air monitoring data;
- An explanation of agency roles and requirements;
- The characterization of airport-related air emissions;
- An emissions inventory / dispersion modeling results for historic (i.e., 1993) conditions; and
- An emissions inventory for actual existing conditions in 1998.

5.4.1 Current Air Quality Conditions and Regulatory Criteria

5.4.1.1 Criteria Air Pollutants and Air Quality Standards

The US Environmental Protection Agency (EPA) has established National Ambient Air Quality Standards (NAAQS) for the following six "criteria" pollutants: carbon monoxide (CO), nitrogen dioxide (NO_2), sulfur dioxide (SO_2), particulate matter (PM), ozone (O_3), and lead (Pb). The Massachusetts Department of Environmental Protection (DEP) has adopted these same standards.

The concentrations of these criteria air pollutants serve as indicators-of-quality of the outdoor (i.e., ambient) atmosphere. Notably, some criteria pollutants, like O_3, occur regionally (e.g., over many square kilometers); others, like CO, only disperse locally (i.e., over several square kilometers); and some, like PM, have characteristics that can be both regional and local. Those that are emitted directly into the atmosphere are called "primary" pollutants (e.g., CO and PM) in contrast to "secondary" pollutants (e.g., O_3), which are produced in the atmosphere from precursors (e.g., volatile organic compounds [VOCs] and NO_2). A general discussion of the EPA / DEP six criteria air pollutants is shown below in Table 5.4-1 and a detailed discussion of each can be found in Section 5.3-1 of the Airside Project Draft EIS / EIR.

Table 5.4-1
Sources of Criteria Pollutants

Pollutant	Major Sources of Pollutant
Carbon Monoxide (CO)	Natural and manmade; motor vehicles; incomplete combustion of fuels; fossil fuel combustion in utility and industrial boilers.
Nitrogen Dioxide (NO_2)	Natural and manmade; lightning, forest fires, combustion of fossil fuels in motor vehicles and utility/industrial boilers.
Particulate Matter (PM_{10}, $PM_{2.5}$)	Natural and manmade; emissions from fuel combustion; open burning, material handling, dust producing industries, fugitive dust; wind erosion, forest fires; sea spray.
Sulfur Dioxide (SO_2)	Natural and manmade combustion of sulfur bearing fuels (coal, oil, gasoline, diesel) and industrial processes.
Ozone(O_3)	Natural and manmade sources of NO_2 and VOCs, which are released during fuel combustion in engines, electric power generation units and space heaters, lead to formation under certain atmospheric conditions.
Lead (Pb)	Burning of lead-containing fuels and manufacturing.

The Massachusetts and NAAQS standards for these six criteria air pollutants are summarized in Table 5.4-2. Concentration units are micrograms of pollutant per cubic meter of air ($\mu g / m^3$). Notably, the one-hour value for NO_2 is a MA DEP policy guideline (not a regulatory standard in Massachusetts) which is only applicable to major stationary sources emitting over 250 tons / year of NO_2. Although it is not applicable to Logan in a regulatory sense, Massport has used this guideline value in the past in interpreting NO_2 measurements taken at and near runway ends. In general, for standards based on 24-hour (or less) averaging times, the second-highest concentrations are used to determine compliance with these standards. The U.S. EPA has recently introduced some changes to the O_3 and PM standards, which are reflected in Table 5.4-2.

5.4.1.2 Air Monitoring Information

The MA DEP, Division of Air Quality Control, Air Quality Surveillance Branch maintains a network of ambient air monitoring stations throughout the Commonwealth, including three in the general vicinity of Logan. Measurements of criteria air pollutants, their precursors, and meteorological conditions are recorded at these stations on a routine basis.

Table 5.4-2
Massachusetts and National Ambient Air Quality Standards

Pollutant	Averaging Time	Standard ($\mu g/m^3$)
CO	1-hour	40,000
	8-hours	10,000
NO_2	1-hour [1]	320
	Annual	100
PM_{10} ($PM_{2.5}$) [2,3]	24-hours	150 (65)
	Annual [4]	50 (15)
SO_2	3-hours	1,300 (secondary) [5]
	24-hours	365
	Annual	80
O_3	1-hour	235
	8-hours [3]	157
Lead	Calendar quarter arithmetic mean	1.5

1 DEP policy guideline for NO_2 applicable only to major stationary sources.

2 PM_{10} and $PM_{2.5}$ encompass particulate matter with diameters less than or equal to 10 and 2.5 microns, respectively.

3 The status of these standards is unsettled because of recent judicial action, but they are still in place.

4 The PM_{10} standard is based upon an estimated exceedance calculation described in Appendix K of the Airside Project Draft EIS/EIR of 40 CFR Part 50. The annual standard is met if the estimated annual arithmetic mean concentration does not exceed 50 $\mu g/m^3$.

5 Secondary standards are set to protect public welfare.

Source: Massachusetts Air Quality Standards, Title 310, Section 6.00 and 40 CFR 50.4-50.12.

The closest of these DEP air monitoring stations to Logan is located in East Boston, at 340 Bremen Street. Located adjacent to the northwest boundary of the airport, approximately 0.5 miles from Runway 15R, ambient concentrations of CO, SO_2, PM_{10}, and NOx (NO and NO_2) are recorded at this site (see Figure 5.4-1 for location). Another MA DEP station is located at the eastern portal of the Sumner/Callahan Tunnels (approximately 0.5 miles from Logan). This station will pick up CO levels from vehicles, including airport-related, passing into and out of the tunnels. The next closest DEP monitoring station is located on Powder Horn Hill in Chelsea. This is the closest O_3 monitor to Logan Airport. NO_2 and SO_2 are also monitored at this site.

A synopsis of the most recent monitoring data for these stations is provided in Table 5.4-3. As shown, there have been no violations of the NAAQS at the monitoring stations for any criteria air pollutant in at least the past five years.

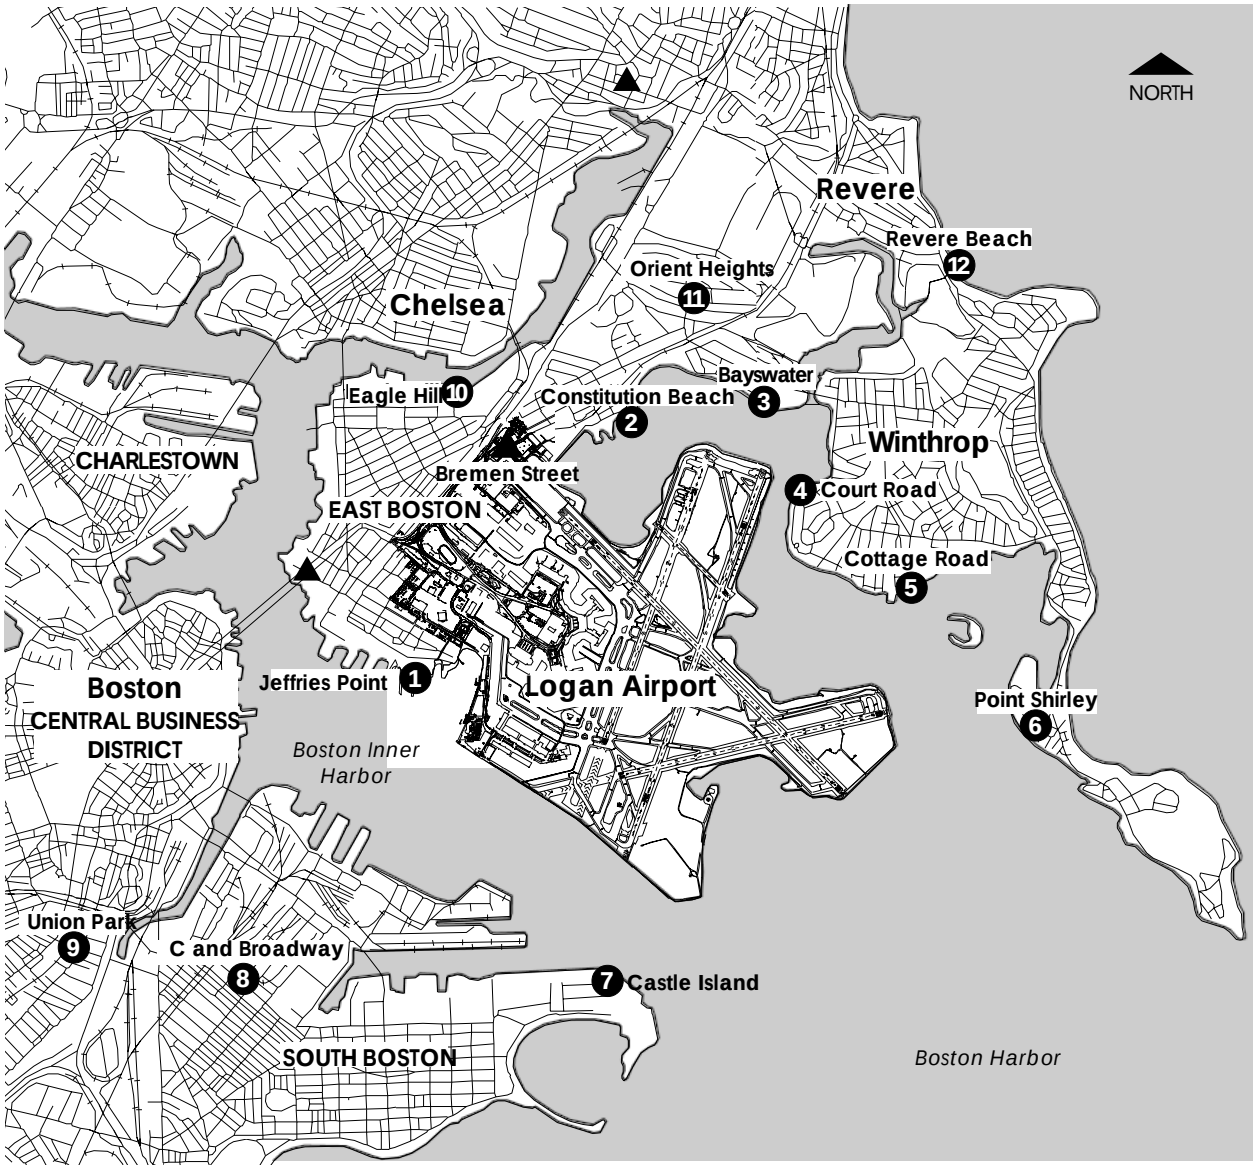
The following summaries generally describe these data.

- **Carbon Monoxide.** CO is an air pollutant characterized by ambient concentrations that correlate closely with local motor vehicle traffic and meteorological conditions. As a result, the Bremen Street station shows some variability in both the one- and eight-hour CO concentrations over the past five years. This is likely attributable to the influences of traffic, wind, and temperature in the immediate vicinity of the monitor. CO concentrations at the Sumner/Callahan Tunnels site are also heavily influenced by motor vehicle traffic passing into and out of the tunnel. Airport-related vehicles constitute approximately one-half the total tunnel traffic. Notwithstanding the above, CO levels at these two locations have remained well within the one- and eight-hour NAAQS over the past several years.

- **Nitrogen Dioxide.** The monitoring data from the Bremen Street site show neither an upward nor downward trend in NO_2 over the past several years. This is reflected in both the one-hour and annual mean concentrations.

- **Particulate Matter.** With only one exception, the highest 24-hour PM_{10} concentrations at the Bremen Street site have not exhibited a wide variability over the past few years. The annual mean PM_{10} levels similarly have not changed substantially over time. Although the $PM_{2.5}$ monitoring program has begun, the measurements are not yet available through the EPA. The $PM_{2.5}$ and eight-hour O_3 standards have been the subject of litigation, which is described in Section 5.4.1.3.

- **Sulfur Dioxide.** Since 1993, SO_2 levels exhibit slight downward trends at the Bremen Street and Chelsea Station sites.



LEGEND

- ● Modeling Receptors
- ▲ Monitor Location

Figure 5.4-1

Air Quality Modeling Receptor Locations

7466-FIG-5.4-1.pm65

- **Ozone.** O_3 is not measured at the Bremen Street station. The closest MA DEP ozone monitor to Logan is located at the Soldiers Home on Powder Horn Hill in Chelsea, Massachusetts, approximately 1.5 miles to the northwest. However, as previously discussed, O_3 is a regional air pollutant. Therefore, the monitoring data collected at the Chelsea site is considered representative of O_3 concentrations throughout the Chelsea / East Boston area. As shown in Table 5.4-3, between 1993 and 1997 the second highest one-hour O_3 concentrations have followed a downward trend. This trend turned slightly upward in 1998. Notably, no violations at the NAAQS for O_3 have been recorded at this site since 1992. Not enough data for the eight-hour averaging time are available to establish a trend. Data from 1997 to 1999 will be used to evaluate the area's compliance with the eight-hour standard, should this standard be implemented and become enforceable by the EPA.

Massport NO_2 Monitoring Program

Since 1982, Massport has collected ambient NO_2 data using diffusion tubes at up to 27 locations (on- and off-airport) in the vicinity of Logan. An analysis of the most recent results and historic trends can be found in the *1999 Environmental Status and Planning Report (ESPR).* The highest NO_2 concentrations recorded in the communities occur in locations that are likely not affected by emissions from Logan. For example, the station with the highest NO_2 concentration in 1997[16] was at Maverick Square and the elevated levels are likely due to the heavy motor vehicle traffic in the Sumner / Callahan Tunnels, Maverick Square and local traffic nearby. No violations of the NAAQS have been recorded at any of the off-airport sites and residential communities.

Soot Measurements

In response to complaints raised by residents living near Logan regarding soot and oily deposits, Massport commissioned two separate, but complementary, scientific studies to help establish the exact nature of this atmospheric fallout, the results of these studies are presented in Section 5.3.1.3 of the Airside Project Draft EIS / EIR.[17],[18]

Odor Assessment

Massport has also conducted an assessment of odor complaints received from communities surrounding the airport, the results of which can be found in Section 5.3.1.2 of the Airside Project Draft EIS / EIR.

CO (ppm)	2nd Highest 1-Hour	7	8	5	7	5	3	35
	2nd Highest 8-Hour	4	5	3	3	4	4	9

Notes:
1 National Ambient Air Quality Standards, except for the case of the 1-hour NO_2 level, which is a MA DEP policy guideline applicable only to major stationary sources.
2 Located at 340 Bremen Street, East Boston.
3 As stated previously, the second-highest concentrations are used to determine NAAQS compliance for this averaging time.
4 Based on PM_{10} data; $PM_{2.5}$ data are unavailable.
5 Located at Soldiers Home, Powder Horn Hill, Chelsea.
6 Based on 1-hour O_3 measurements.
7 Data from years before 1995 are unavailable for this averaging time. The standard states that the average of the annual 4th highest daily 8-hour maximum over a three-year period is not to exceed 0.08 ppm. Therefore, a single exceedance does not constitute a violation of the standards. This standard is not currently enforceable, although it remains in place.
8 Located at portal to Sumner Tunnel at Visconti Street.

5.4.1.3 Attainment/Non-attainment Designations

In accordance with the Federal Clean Air Act (CAA), all areas within the State of Massachusetts are designated as either attainment, non-attainment, unclassifiable, or maintenance with respect to the NAAQS. Simply stated, areas that meet the NAAQS are designated as attainment. Conversely, areas that have violated the NAAQS are designated as non-attainment. Classifications (or degrees) of non-attainment areas are also given as extreme, severe, serious, and moderate. Areas where data are insufficient for classification as either attainment or non-attainment are designated as unclassifiable. Finally, areas that have been re-designated from nonattainment to attainment since 1990 are labeled maintenance.

As shown in Table 5.4-4, the airshed around Logan is designated by MA DEP as an attainment area for CO, NO_2, SO_2, PM_{10}, and Pb meaning that the NAAQS for these five criteria air pollutants are being met. As explained below, the study area is classified as a nonattainment area for O_3.

In June 1999, the Boston-Lawrence-Worcester area was identified as an area that attains the one-hour ozone standard and, as such, an area where the one-hour standard no longer applies. A May 1999 D.C. Circuit Court case, however, questioned the EPA's authority to set the new ozone and particulate matter standards. Because of this case, the EPA had no authority to implement the eight-hour standard, which applied once the one-hour standard was attained. In order to provide some form of ozone standard, the EPA reinstated the one-hour ozone standard nationwide. In doing this, the EPA designated attainment classifications for nearly 3,000 counties, including Suffolk County, which has been reclassified as *serious nonattainment*. At the Chelsea monitoring station (1.5 miles northwest of Logan), the last exceedance of the 1-hour O_3 standard occurred in 1991. On February 27, 2001, the Supreme Court rejected the D.C. Circuit Court's findings and upheld the EPA's authority to set the revised O_3 and $PM_{2.5}$ standards. However, the revised standards are not immediately subject to implementation because the Supreme Court is requiring the EPA to revisit its implementation policy, specifically for O_3. The EPA must develop a reasonable interpretation of the non-attainment implementation provisions of the CAA.

Table 5.4-4
Attainment/Non-Attainment Designations for the Boston Area[1]

Pollutant	Designation	Classification
Carbon monoxide (CO)	Attainment	N/A
Sulfur dioxide (SO_2)	Attainment	N/A
Ozone (O_3)	Non-attainment (1)	Serious
Nitrogen dioxide (NO_2)	Attainment	N/A
Particulate matter (PM_{10})	Attainment	N/A
Lead (Pb)	Attainment	N/A

1 Designated area is Boston-Lawrence-Worcester.
N/A not applicable.

The Massachusetts State Implementation Plan (SIP) for O_3 identifies the strategies that have been, and will be, implemented to reduce emissions of VOCs and NOx to target levels needed to achieve compliance. In the Boston area, the Boston Metropolitan Planning Organization (MPO) works closely with the MA DEP to develop and update the SIP, Rate-of-Progress Plans and other supporting materials. In addition, the MPO is responsible for implementing the emissions reduction strategies presented in the SIP in this area. As a member of the Boston MPO, Massport plays a key role in this process. For example, all of Massport's planning efforts are developed to be consistent with the policies in the SIP including the East Boston / Logan parking freezes.

5.4.2 Sources of Air Emissions

5.4.2.1 Airport-Related Sources of Air Emissions

In general terms, the primary sources of air emissions at major air carrier airports such as Logan are aircraft, ground service equipment (GSE), and motor vehicles. Other sources include fuel storage facilities and transfer operations, a variety of other stationary sources (e.g., space heating, emergency electrical generation, food preparation), and construction activities. Table 5.4-5 provides a listing of air emissions sources at Logan, the pollutants emitted, and their general characteristics.

These emissions are described in greater detail in the Airside Project Draft EIS/EIR, Section 5.3.2.1. The amounts of emissions generated by these sources are given later in Sections 5.4.3.2 and 6.4.2 in the form of existing and future-year air emission inventories.

5.4.2.2 Modeled Emissions

For the purposes of evaluating the air quality impacts attributable to a project, it is important to distinguish between “direct” and “indirect” emissions. Direct emissions are generally defined as air pollutants, or their precursors that are caused directly by the project, including its construction, and occur at the same time and place as the action. Aircraft taxi, takeoff roll, landing, and delay periods; GSE; fuel storage and distribution facilities; on-site motor vehicle traffic; and stationary point sources (i.e., steam boilers and electrical generators) are all potential generators of direct emissions.

By comparison, indirect emissions are caused by the project, but

- Occur later in time,
- Are removed in distance, and
- Are reasonably foreseeable.

Examples may include off-site airport-related motor vehicle traffic. All other emissions, such as those from non-airport motor vehicle traffic or ancillary development are considered incidental, or "background" as they are not caused by the project and are not controllable or anticipated by the sponsor.

Table 5.4-5
Sources of Air Emissions

Sources	Emission(s)	Characteristics
Aircraft	Carbon monoxide Volatile organic compounds Nitrogen oxides Particulate matter	Exhaust products of fuel combustion which vary greatly depending on aircraft engine type, power setting, and period of operation. Except for short periods of take-off and approach, aircraft altitude precludes measurable off-site ground level impacts.
Ground service vehicles and equipment	Carbon monoxide Volatile organic compounds Nitrogen oxides Particulate matter	Exhaust products of fuel combustion (diesel, gasoline, and natural gas) from service trucks, tow tugs, belt loaders, and other portable equipment.
Fuel storage and transfer facilities	Volatile organic compounds	Formed from the evaporation and vapor displacement of fuel from storage tanks and fuel transfer facilities. Emissions vary with fuel use, type of storage tank, refueling method, fuel type, vapor recovery system, climate, and ambient temperature.
Space heating and emergency electrical generation facilities	Carbon monoxide Volatile organic compounds Nitrogen oxides Particulate matter Sulfur dioxide	Exhaust products of fossil fuel combustion from boilers dedicated to indoor heating requirements and emissions from incinerators used for waste reduction. Emissions are permitted by MA DEP, and are generally well controlled with operational techniques and post-burn collection methods.
Motor vehicles	Carbon monoxide Volatile organic compounds Nitrogen oxides Particulate matter Sulfur dioxide	Exhaust products of fuel combustion from passenger, employee, and cargo traffic approaching, departing, and moving about the airport site. Emissions vary greatly depending on vehicle type, distance traveled, operating speed, and ambient conditions. On-site emissions are confined to access/egress roadways and parking facilities.
Construction activities	Carbon monoxide Volatile organic compounds Nitrogen oxides Particulate matter Sulfur dioxide	Dust (e.g., soil and concrete) generated during construction and land-clearing activities released into the air by wind and machinery. The amount of particulate emissions varies with the material type, the amount of area exposed, wind, rain, and the use of Best Management Practices to reduce fugitive dust. Also includes emissions from construction vehicle exhaust.

5.4.2.3 Previous Air Quality Impact Assessments

The assessment of air quality impacts associated with Logan is an ongoing process that is continually updated. Table 5.4-6 summarizes some important mileposts in this process.

The results contained in these studies compare favorably with each other largely because forecasts of aircraft operations were generally consistent. Any differences in the results are attributable to updated emission factors, fleet mix characteristics, and/or ground-based delay periods. Moreover, there were no significant increases in airport-related emissions and no predicted violations of any NAAQS.

Table 5.4-6
Previous Air Quality Impact Assessments

Project/Assessment	Analyses
Logan Airside Project Improvements Feasibility Study - Phase 1 Report	Simulation of 1993 and 1999 conditions using the Logan Dispersion Modeling System to predict ambient levels of CO, HC, NO_2, PM_{10}, and odor at six community receptors.
Logan GEIR 1994/5; Annual Updates 1993 and 1996-98	Annually updated air emission inventories of VOCs, NOx, and CO from all Logan sources and calculated both on and off the airport for the years 1987, 1990, 1993-97, 1999 and 2010.
1991/1992 Final Logan GEIR (1993)	In addition to analysis listed above, microscale atmospheric dispersion modeling for CO at several Logan receptors and receptors in the surrounding communities.
Logan Growth and Impact Control (LOGIC) Study(1993)	Emission inventories and atmospheric dispersion modeling for 1987 and 2010.
West Garage Project Draft and Final EIR (1994 and 1995)	Emission inventories for 1993, 1996, and 1999; microscale CO dispersion modeling for landside motor vehicle traffic.
International Gateway Draft and Final EIR and Environmental Assessment (1996)	Used future year emissions inventories of all Logan airside-related sources and determined that reduced hardstand use resulted in air quality benefits.

5.4.3 Existing and Historic Air Emissions and Dispersion

In order to establish a benchmark of existing air quality impacts associated with Logan, an air emission inventory and atmospheric dispersion modeling was conducted for 1993 conditions. This procedure is consistent with FAA guidelines for preparing an EIS and meets the MEPA requirements for this project. Essentially, this analysis permits the comparison of future year forecasts to current year conditions.

The approach for conducting this work is summarized below followed by separate presentations of the emission inventory and dispersion modeling results.

5.4.3.1 Assessment Approach

The approach for quantifying the Airside Project 1993 baseline air quality conditions was subdivided into two elements: an emissions inventory and atmospheric dispersion modeling.

The emissions inventory serves several purposes: First, the various sources of air emissions identified in the Airside Project Draft EIS/EIR Section 5.4.2.1 (i.e., aircraft, ground service equipment, motor vehicles, fuel facilities, etc.) are individually quantified, thus apportioning the relative contribution of each source. Second, the results are compared to other previous analyses discussed in the Airside Project Draft EIS/EIR Section 5.4.2.3 in order to insure consistency among the various assessments. Third, when compared to future year conditions (presented in the Airside Project Draft EIS/EIR Section 6.4.2) the effect of growth and, more importantly, the Airside Project on air emissions can be evaluated. Finally, the emissions inventory serves as important input to the atmospheric dispersion model.

Because the emission inventory results are not directly comparable to the NAAQS, atmospheric dispersion modeling is also conducted. Using the emission inventory data, combined with a full year of meteorological data, predictions of ambient pollutant concentrations are made.

The Logan Dispersion Modeling System and FAA/EPA methods were used to develop the emission inventories and perform the dispersion modeling. The modeling input parameters, assumptions and assessment methods are described in detail in Airside Project Draft EIS/EIR Section 6.4.

5.4.3.2 1993 Historic Modeled and 1998 Actual Condition Emissions Inventories

This section presents the results of the emissions inventory for the 1993 Historic Modeled Condition, followed by the results of the emissions inventory for the 1998 Actual Condition.

The results of the Airside 1993 Historic Modeled Condition emissions inventory for Logan are contained in the Airside Project Draft EIS/EIR Table 5.4-7. For comparison, the GEIR results for 1993 are also shown. The results of the 19*98 Annual Update* Emissions Inventory are shown in Table 5.4-8. Given in units of kilograms (kg) per day (1 kg = 2.2 pounds), emission totals are given for the pollutants CO, NOx, and VOCs for both 1993 and 1998 and for PM_{10} in 1993. For ease in viewing these data, Figures 5.4-2 and 5.4-3 provide illustrative summaries in the form of pie-charts of the 1993 and 1998 Emissions Inventories, respectively.

As shown for both 1993 and 1998, aircraft and GSE constitute the two largest sources of CO at Logan, each representing between 41 and 44 percent, respectively, of the total in both years. Airport-related motor vehicles, which represent the third largest CO source, contributed ten percent of the total CO in both 1993 and 1998. Other sources are negligible in both years.

Aircraft also constitute the majority (approximately 75 and 80 percent, respectively) of the NOx emissions in 1993 and 1998. This is primarily attributable to high-power operating modes (i.e., take off and climbout). GSE and airport-related motor vehicles are again the second and third largest sources of NOx emissions, respectively, in both years.

Table 5.4-7
1993 Modeled Condition Emissions Inventory for Logan (kg/day)[1]

Source Categories	CO	NOx	VOC	PM_{10} [2]
Aircraft [3]	**7,060**	**3,811**	**2,410**	**208**

1993 Data from *GEIR* [5]	**17,704**	**5,964**	**4,501**	**N/A**
(tpy)	**(7,122)**	**(2,399)**	**(1,811)**	

1 For consistency with previous analyses, units of kg/day are used. 1 kg/day is equal to 0.4023 tons per year (tpy).
2 Assumes all PM emissions are PM_{10}
3 Includes air carriers, commuter, cargo, and general aviation aircraft throughout the entire landing/take-off cycle (i.e., approach landing, taxi-in, taxi-out, take-off, and climb-out, including any delay periods).
4 Includes the central heating/cooling plant and emergency electricity generation.
5 *1997 Annual Update, Logan Airport GEIR*, August 1998. Not included in *1998 Annual Update*.

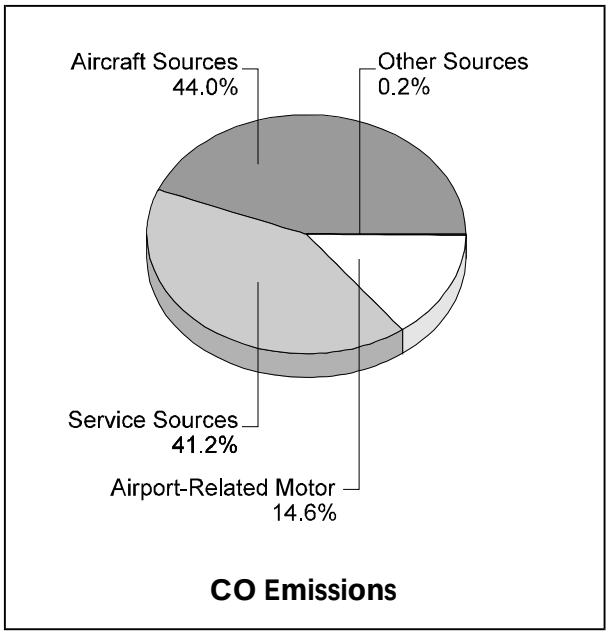
Table 5.4-8
***1998 Annual Update* Emissions Inventory for Logan (kg/day)**

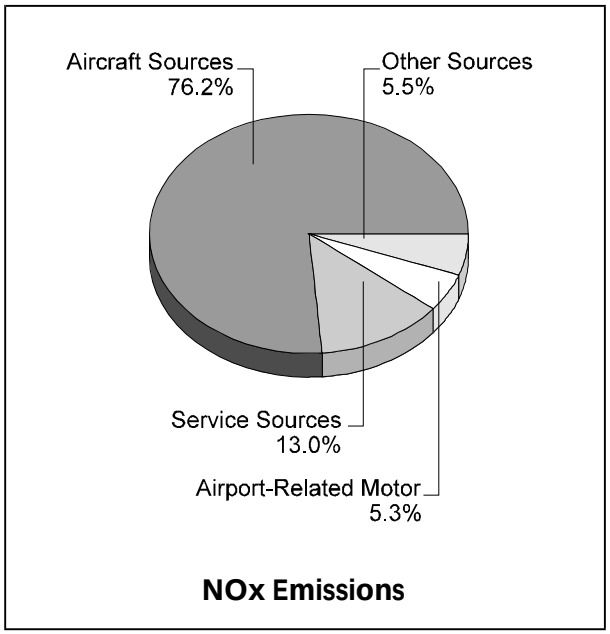
Source Categories	CO	NOx	VOC
Aircraft [1]	**5,577**	**4,685**	**1,648**
Service Vehicles [2]	**5,787**	**608**	**496**
Airport-Related Motor Vehicles			
Parking/Curbside	587	24	102
On-airport motor vehicle sources [3]	1,332	252	212
Total Motor Vehicle Sources	**1,919**	**276**	**314**
Other Sources			
Fuel storage/handling	0	0	372
Miscellaneous sources [4]	37	284	2
Total Other Sources	**37**	**284**	**374**
Total Airport Sources	**13,320**	**5,853**	**2,832**
(tpy)	**(5,359)**	**(2,355)**	**(1,139)**

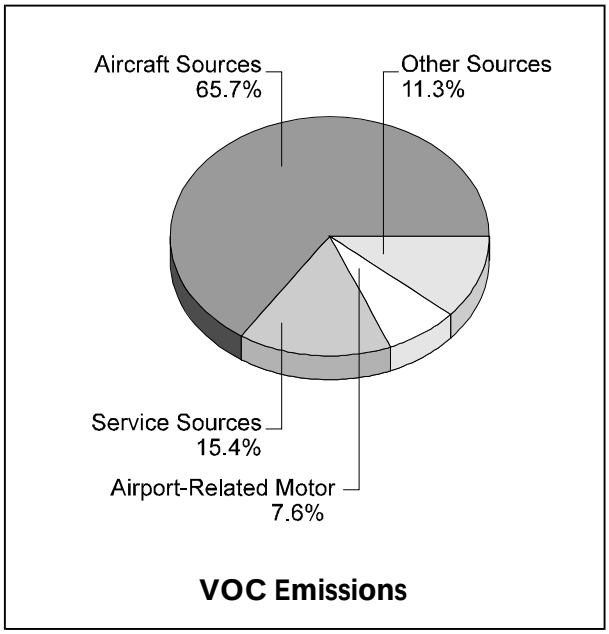
1 Includes air carriers, commuter, cargo, and general aviation aircraft throughout the entire landing/take-off cycle (e.g., approach landing, taxi-in, taxi-out, take-off, and climb-out, including any delay periods).
2 Includes vehicles and equipment converted to alternative fuels.
3 Includes through traffic from the Ted Williams Tunnel not destined for Logan Airport.
4 Includes the Central Heating and Cooling Plant and emergency electricity generation.

Similarly, aircraft emissions of VOCs represent 65 and 58 percent of the airport total in 1993 and 1998, respectively, followed by GSE at 15 percent in 1993 and 18 percent in 1998. Fuel storage and transfer operations, classified under "other sources," emit roughly 11 percent of the total VOCs in 1993 and 13 percent in 1998. Emissions of PM_{10} in 1993 are generated primarily by aircraft (86 percent) followed by motor vehicles, GSE, and other sources.

When compared to the 1993 emissions inventory as presented in the *1997 Annual Upda*te, the Airside Project results are lower. This difference arises from the availability of updated emission factors for aircraft, service vehicles, and motor vehicles and the refined assessment of airfield operational conditions developed in support of this Airside Project Supplemental DEIS/FEIR







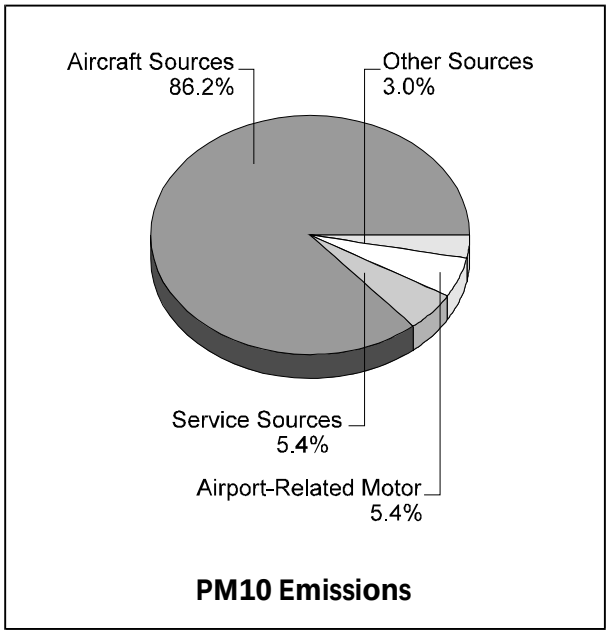


Figure 5.4-2
1993 Baseline Emission Inventory

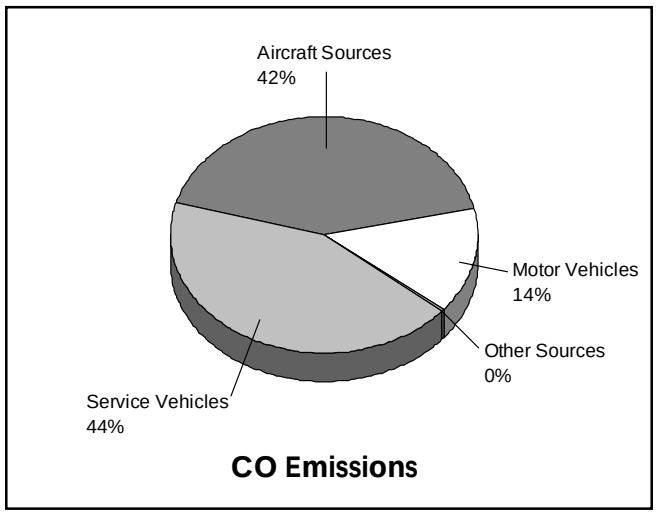

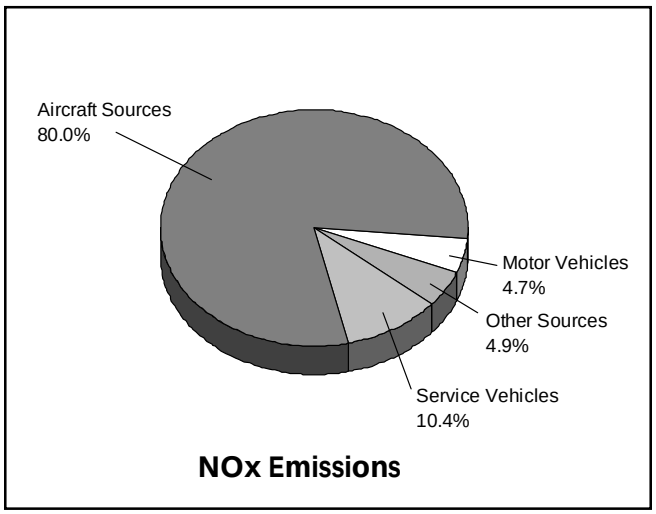

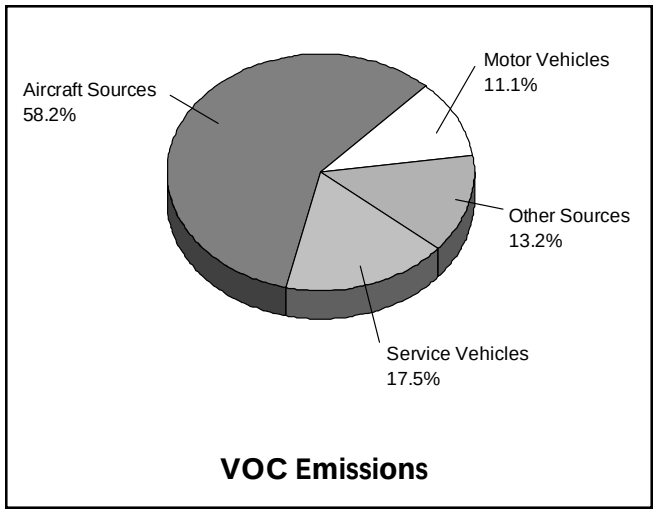

Figure 5.4-3
1998 Annual Update Emission Inventory

7466-FIG-5.4-3.p65

Off-site motor vehicle emissions associated with Logan were computed separately and are presented in Table 5.4-9. Representative of "indirect emissions," this source is subdivided into two categories: (1) Motor vehicle emissions generated on local streets within the East Boston Area and (2) emissions generated by motor vehicles traveling to and from the airport on major regional highways and arterials.[23] For comparative purposes, emissions attributable to non-airport-related motor vehicles on these same roadway networks are also shown. These off-site motor vehicle emissions were computed from traffic data contained in the *1994/95 GEIR* and MOBILE5b emission factors.

1 Airport-related motor vehicles using local East Boston streets.
2 Assumes all PM emissions are PM_{10}
3 Airport-related motor vehicles on major regional arterials.
Note: Not conducted for the *1998 Annual Update*.

[23] The regional study area for the air quality assessment includes access routes to Logan Airport and major highways that are significant carriers of airport-related traffic. Roadways include Route 1 (north of Boston); I-93/Route 3 (south of Boston); and I-90/ Massachusetts Turnpike (west of Boston). The limits of the regional study area for vehicle travel analyses are defined by the intersection of these radial highways with I-95/Route 128.

5.4.3.3 Dispersion Model Results for 1993

For the purposes of this assessment, ambient levels of air pollutants were predicted at 12 community sites (receptors) in the vicinity of the airport. (See Figure 5.4-1 for receptor locations.) Using the Logan Dispersion Modeling System (LDMS) and 1993 local meteorological data, the model results were combined with appropriate "background" concentrations to obtain these levels. For ease in assimilating these findings, only the highest levels predicted from among all 12 receptors are reported in Table 5.4-10. Even these fall below the NAAQS. Appendix F provides a complete presentation of dispersion modeling results. A comparison between LDMS and the FAA's Emissions Dispersion Modeling System (EDMS) is provided in Section 6.4.1, of Chapter 6, Environmental Consequences.

Exceptions to this reporting technique are the reported ozone and odor indicator levels, which are given as spatially averaged values. The highest spatial average of 24-hour VOC concentrations (as ozone indicators) are not predicted to be higher than 20 (μg / m3). One-hour VOC levels (as odor indicators) are shown to be below 121 (μg / m3). There are no NAAQS for these pollutants. Rather, these results will be used in Section 6.4 for comparison to future year conditions with and without the Preferred Alternative.

Table 5.4-10
1993 Dispersion Model Results Summary

Pollutant/Parameter(1)	Community Air Concentration ($\mu g/m^3$)	Air Quality Standard ($\mu g/m^3$)
CO, 1-hour 1	6,840	40,000
CO, 8-hour 1	3,311	10,000
NO_2, 1-hour 1	257	320
NO_2, annual, highest	60	100
PM_{10}, 24-hour 1	50	150
PM_{10}, annual, highest	23	50
Ozone indicator, Total VOCs, 24-hour, spatially-averaged highs	20	N/A
Odor indicator, Aircraft Idle Mode VOCs, 1-hour, spatially-averaged highs	121	N/A

1 The "highest second high" data are provided as the maximum value determined by taking the second highest value of the dispersion modeling results at each receptor and then reporting the maximum value for that data set of twelve. (Background levels are included).

N/A There are no standards applicable to this pollutant, which is used as an indicator of potential ozone or odor formation.

Note: Not conducted for the *1998 Annual Update*.

5.5 Biotic Communities

Biotic Communities refers to the vegetation communities, water resources, and wildlife habitats of an area. The ecosystems of the project area consist primarily of the upland vegetative communities associated with the Logan airfield. The urban character of the project area limits the extent of upland vegetation, and hence, wildlife habitat.

5.5.1 Vegetation

Vegetation occurring on the airfield, including the area of the Centerfield Taxiway and other vegetated areas proposed for construction, is primarily herbaceous, with some areas of sparse vegetation and bare ground. Herbaceous vegetation is regularly mowed to a maximum height of approximately 6 inches. The plant community consists of grasses and forbs characteristic of lawns, fields, and upland coastal habitats.

5.5.2 Wetlands

While federal and state-regulated wetlands do occur along the perimeter of the airfield (see Figure 5.1-2), no elements of the Airside Project improvements, require work in these wetland resource areas, although certain of the alternatives would unavoidably require construction in the buffer zone.

The rock-faced bulkhead that forms the southern boundary of Logan is considered a Coastal Bank under the Massachusetts Wetlands Protection Act (MGL Chapter 131, Section 40) and associated regulations (310 CMR 10.00 et. seq.). As defined at 310 CMR 10.30(2), Coastal Banks are "the seaward face or side of any elevated landform, other than a coastal dune, which lies at the landward edge of a coastal beach, land subject to tidal action, or other wetland."

The coastal bank is significant to storm damage prevention and flood control. At Logan, this coastal bank was initially constructed to confine materials placed as fill for the airfield. The bank continues to provide storm damage protection along this edge of the airfield. The top of the bank is above the 100-year flood elevation, which is 10 feet above mean sea level for Boston Harbor.

Land within 100 feet of the coastal bank is designated as the "buffer zone," and extends the length of the coastal bank for the perimeter of the airfield. In the area of construction for proposed unidirectional Runway 14/32, the buffer zone presently consists of the airfield perimeter roadway, guard rail, taxiway, and paved runway safety area. Limited areas of grass are also present between the perimeter road and the taxiways and safety areas.

5.5.3 Wildlife

The airfield is an urbanized environment with herbaceous vegetation between paved surfaces such as runways, taxiways, the perimeter road and aprons which is isolated from off-site vegetation by airport facilities and East Boston streets and neighborhoods. The airfield is only accessible to wildlife that is able to fly, travel through an urban environment, or swim via Boston Harbor.

5.5.3.1 Typical Species

As a result of the developed nature of the airfield, difficulty of access and the lack of diversity in cover types, airfield wildlife is low in diversity and predominantly avian. However, some mammals such as muskrats, mice, rats and other rodents have been observed on the airfield.

With regard to avian species, the Logan airfield provides a relatively large expanse of grassland habitat in a region of the country (i.e., New England) dominated by forests. As a result, seasonal migrants associated with this habitat type, such as lapland longspur, snow buntings, killdeer, horned lark, upland sandpipers, and savannah sparrows, have been recorded on the Logan airfield. Snowy owls (*Nyctea scandiaca*) are common winter visitors. A wide range of waterfowl, waders, and shorebirds uses the adjacent marine habitat of Boston Harbor and areas around the airport perimeter that are not seawall. Table 5.4-2 of the Airside Project Draft EIS/EIR provides a list of bird species observed at Logan.

5.5.3.2 Endangered and Threatened Species

Based on correspondence with the U.S. Fish and Wildlife Service (USFWS) dated April 1, 1997, no federal-listed endangered and threatened plant or animal species are known to occur on the Logan airfield. There are also no state-listed plant species known to occur at Logan. (A copy of the letter from the USFWS is included in Appendix G) A copy of the most recent USFWS list dated December 8, 2000, indicates that while the statewide list has been modified, the initial 1997 findings remain relevant.

The upland sandpiper (*Bartramia longicauda*), a state-listed endangered animal species, is associated with the Logan airfield, and this species accounts for mapped habitat shown in the Massachusetts Natural Heritage and Endangered Species Program (NHESP) Massachusetts Natural Heritage Atlas (2000-2001 Edition).

For several years, upland sandpipers have been observed on the airfield during the spring migratory season, breeding and nesting periods, and through the summer. Upland sandpipers typically arrive at Logan airfield in April or early May, although they may arrive as early as the beginning of March, and were observed to nest on the airfield in 1990 and 1996. Since 1996, upland sandpiper have been observed seasonally.

Table 5.4-2 in the Airside Project Draft EIS/EIR summarized field observations for this species made during 1990 and in 1996. The 1990 field observations were made as part of the Central Artery/ Tunnel (CA/T) Project's siting studies for the Governors Island dredged materials storage area.

5.6 Water Quality

This section discusses Boston Harbor water quality and describes Logan's existing drainage system and water quality resulting from existing operations.

5.6.1 Boston Harbor

Boston Harbor, which surrounds Logan on three sides, is classified by the Massachusetts Department of Environmental Protection (DEP) as Class SB water. As defined at 314 CMR 4.00, Class SB waters are to be suitable for primary contact recreation (swimming, boating and other water activities), fishing, industrial water uses and the protection, propagation and growth of fish and wildlife. Many of the intertidal flats surrounding Logan are used for the harvesting of shellfish by Master Diggers. However, because of the presence of combined sewer overflows in the vicinity (not associated with Logan), the shellfish must be depurated before sale. More acres of shellfish beds have recently opened to harvesting due to the construction of combined sewer overflows (CSO) treatment facilities at certain outfall points in Boston Harbor by the Massachusetts Water Resources Authority (MWRA). All of these CSOs are non-Massport structures located off the airport. Water quality has also improved due to efforts by the Boston Water & Sewer Commission to investigate and remove illegal sewage connections by others to the storm drainage systems, and to improve the sewerage collection and treatment system around the harbor and the remainder of the MWRA Service Area. Logan's sewer system does not have any illegal connections to the storm drainage system.

The MWRA collects and analyzes water quality data at various locations around Boston Harbor, three of which are in the general vicinity of Logan. Data from these locations were reviewed and analyzed as the basis for characterizing harbor water quality adjacent to Logan. (See Table 5.5-1 in the Airside Project Draft EIS/EIR) The data indicate that the Class SB water quality standards are being met under average conditions.

5.6.2 Airport Drainage and Water Quality

Stormwater runoff from the airfield discharges to Boston Harbor through a complex drainage system. Airfield runoff flows across the grass infield to catch basins located primarily in the areas between the runways and taxiways. The catch basins are connected by underground drain lines leading to a series of outfalls along the perimeter of the airfield which discharge to Boston Harbor. Groundwater also

discharges through this drainage system in those areas of the airfield where an under drain system exists.
There are also four principal discharge points (West Outfall, Porter Street Outfall, Maverick Street Outfall and North Outfall) which drain the terminal areas and portions of the airfield. These four Logan outfalls are permitted through the EPA's National Pollutant Discharge Elimination System (NPDES) program.

A simplified illustration of the drainage system for the terminal and airfield areas is shown in Figure 5.6-1. As illustrated in the figure, much of the terminal and apron area and portions of the southwest corner taxiway system presently discharges to the West Outfall. The West Outfall incorporates pollution control devices, including a mechanically cleaned bar screen, oil skimmer, grinder pump, sedimentation tank, and an oil / water separator. Oil from the separator is collected in an off-line waste oil storage tank. The remainder of the airfield areas included in the Preferred Alternative drain to the perimeter outfall system.

Massport monitors the quality of its major terminal area discharges as part of the NPDES Permit (Permit No. MA 0000787) that was issued by the U.S. EPA for the four main airport outfalls identified above. Massport and the Logan tenants applied in October 1992, as co-applicants, for an individual NPDES Permit for the entire airport which would supersede the existing permit. The U. S. EPA is expected to issue the draft permit in 2001. In addition, a NPDES Permit (Permit No. MA 0032751) has been issued for discharge from the water treatment facility at the Fire Training Facility.

5.6.3 Airport Deicing

Deicing activities at Logan include both anti-icing, which is to prevent snow and ice buildup, and deicing, which is the removal of snow and / or ice once it has built-up on the ground or on an aircraft. (The term "deicing" as used in this document refers both to anti-icing and deicing.) Massport is responsible for operations relating to the deicing of roadways, runways, and taxiways. Roadways at Logan are treated using salt and sand similar to those used on other public roadways. The runways and high speed turn-offs are deiced by applying a liquid mixture of ethylene glycol, urea, and water in an approximate ratio of 50 percent ethylene glycol, 25 percent urea, and 25 percent water. The rates of application on the runways and taxiway exits are in the range of 0.5 to 1.5 gallons per 1,000 square feet, depending on ground conditions, air temperature, precipitation and other weather factors. Occasionally, taxiways may be deiced in a similar manner, under controlled applications. Aircraft deicing practices and volumes will not change as a result of the Airside Project Improvements.

In the Logan NPDES application, Massport assessed the environmental impact of the discharge of deicing materials to Boston Harbor. The assessment resulted in the conclusion that the deicer applied to the runways does not significantly affect water quality because runway runoff flows overland upgradient of the catch basins; the approximately 50 outlets are dispersed around the airfield; and the glycol deicing compounds are relatively harmless with respect to aquatic toxicity (U.S. Fish and Wildlife Service) and quickly biodegrade. The combination of overland runoff and a

large number of small discharge locations helps to attenuate and disperse the deicing compounds used on the airfield.

During preparation of the NPDES application, runoff samples were collected from the drainage system (Outfall A-12) at the departure end of Runways 22R and 22L (see Figure 5.6-1), and analyzed for a number of water quality parameters. The sampling results related to the deicing activities were briefly summarized in Table 5.2-2 of the Airside Project Draft EIS/EIR.

5.7 Soil/Sediment Characterization

This section contains information on the existing quality of soil and subgrade materials that may be removed or relocated during runway and taxiway construction. It also provides a description of the characteristics of the CA/T Project materials which are managed on Governors Island. Construction will not take place in Boston Harbor and therefore, marine sediment quality is not discussed.

5.7.1 Existing Soil Quality

Construction of the runway and taxiway improvements will require the excavation of unsuitable or excess soils. The Airside Project Draft EIS/EIR contained preliminary information on soil quality based on existing data from previous airfield soil sampling programs. Following the Airside Project Draft EIS/EIR, a soil pre-characterization program was conducted by Massport in July and August 1999 in areas where excavation would be required for construction. The goal of the program was to develop both structural and environmental information to assist in the design and construction of the various airfield improvements. Structural soil data will be used for the engineering design and the environmental data will indicate any areas of possible contamination and provide guidance on reuse of the excavated materials, where appropriate.

The soil pre-characterization program involved the installation of 93 soil borings within or in proximity to airside areas proposed for construction of runway and taxiway improvements. Soil samples were collected at three depths from each of the 93 boring locations: 0 - 2 feet below ground surface, 5-7 feet below ground surface, and 8-10 feet below ground surface. In addition, soil borings on Governors Island (B-46, B-47, B-50 and B-51) were installed to a depth of 20 feet below ground surface due to the presence of fill in that area. None of these soil borings were within of 100 feet of wetlands or waterways regulated under the Massachusetts Wetlands Protection Act.

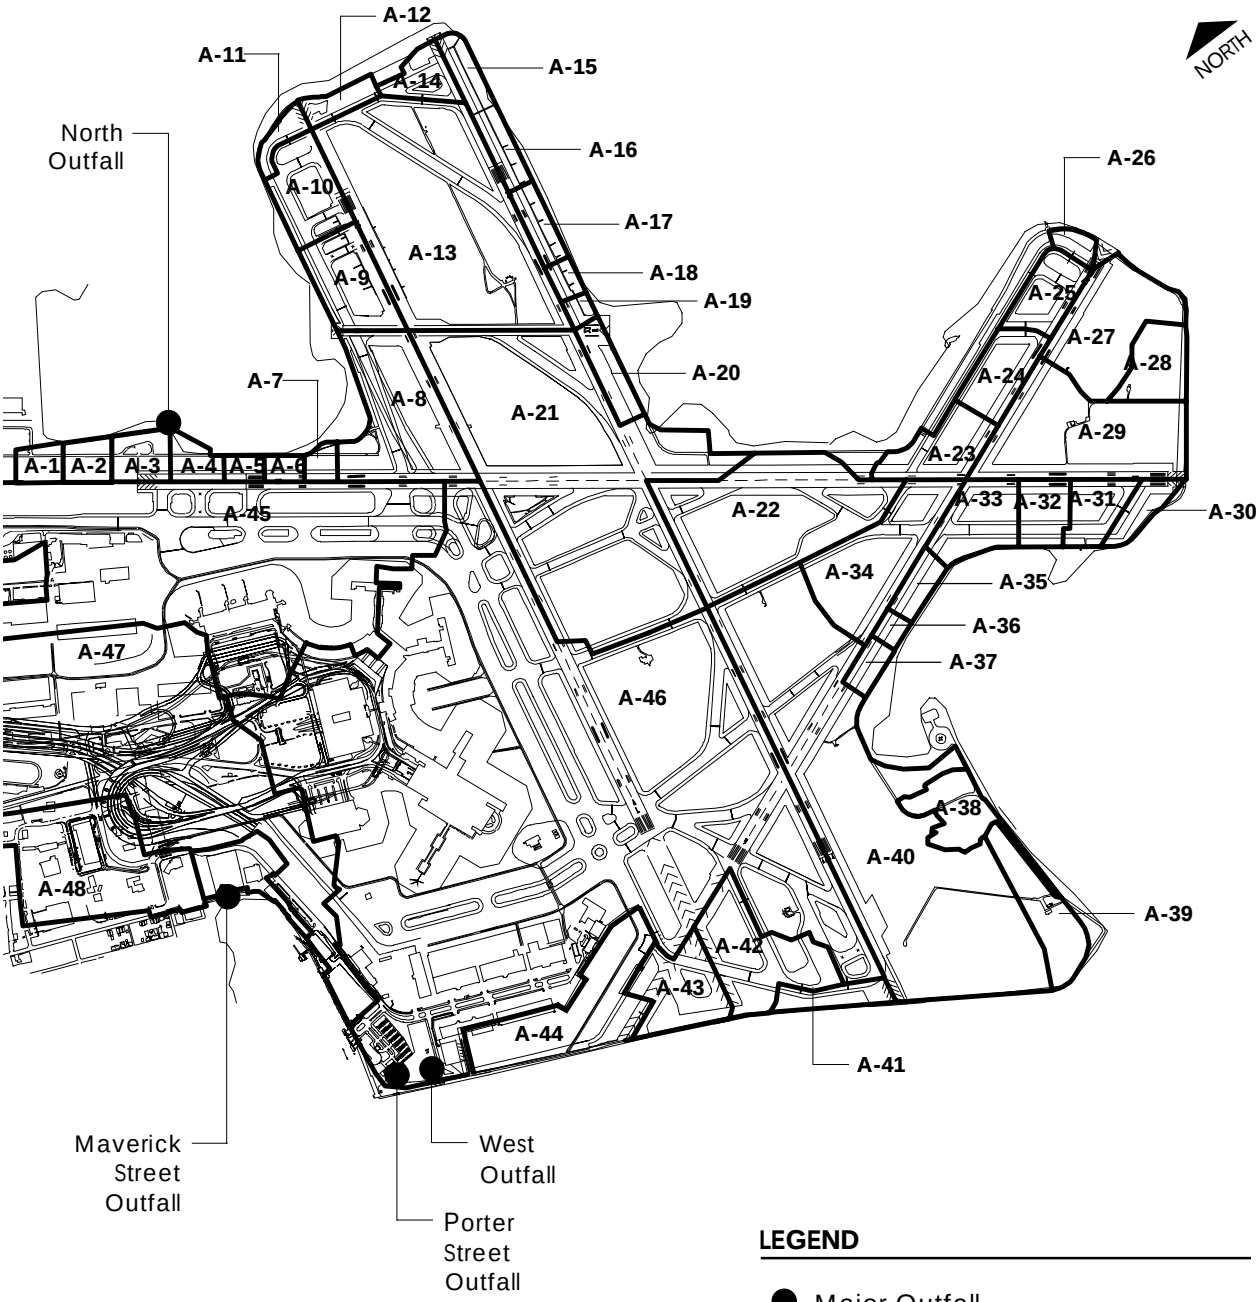

Figure 5.6-1

Existing Drainage Areas

7466-FIG-5.6-1.pm65

Soil samples were analyzed at a DEP-certified analytical laboratory for the following parameters:

- Volatile petroleum hydrocarbons (VPH) and extractable petroleum hydrocarbons (EPH), DEP method 98-1
- Priority pollutant metals, EPA methods 6010/7471/7740/7840
- Pesticides and polychlorinated biphenyls (PCBs), EPA Method 8080
- Soil conductivity, EPA method 120.1/9050

The Massachusetts Contingency Plan (MCP) contains categories for reporting contamination of oil and hazardous materials. These reporting categories are based on land use and groundwater use. Reporting Category S-1 applies to soil that is within 500 feet of dwellings, residentially zoned property, schools, playgrounds, recreational areas, parks and within areas that have been designated as part of groundwater aquifer supply zones. Reporting Category S-2 is for all other land areas. For Logan, the S-2 Category applies. If soil contamination levels exceed the applicable Reportable Concentrations (RC) for oil and hazardous materials, they are considered to be regulated and must be reported to the DEP.

The S-1 and S-2 categories have specific contamination concentrations for oil and hazardous materials. The laboratory results were compared to S-2 Reporting Concentrations established in the MCP at 310 CMR 40.1600. The Toxicity Characteristic Leaching Procedure (TCLP) test is one measure of the toxicity of a sample and upon exceeding regulatory limits it is determined to be TCLP hazardous. The data indicate that the soil was not found to be TCLP-lead hazardous. There are, however, areas where the DEP's Reportable Concentrations are exceeded for various chemical constituents. The analytical results of the soil pre-characterization program are summarized in Table 5.7-1 and are described below.

5.7.1.1 Runway 14/32

The soil pre-characterization data indicate that the soil under the footprint of the proposed unidirectional Runway 14/32 does not exceed the Reportable Concentrations for S-2 soil.

Table 5.7-1
Airfield Soil Data Summary for Exceedances of S-2 Reportable Concentrations

Soil Contaminants	Reportable Concentration S-2 Soil	Proposed Runway 14/32	Proposed Centerfield Taxiway	Proposed Taxiway November Realignment	Proposed Southwest Corner Taxiway Realignment
Total Petroleum Hydrocarbons (mg/kg)					
Volatile Petroleum Hydrocarbons		No Exceedance	No Exceedance	No Exceedance	No Exceedance
Extractable Petroleum Hydrocarbons					
Aliphatic Hydrocarbons		No Exceedance	No Exceedance	No Exceedance	No Exceedance
Polynuclear Aromatic Hydrocarbons (PAHs)		No Exceedance			
Benzo(a)anthracene	1	No Exceedance	ND-19[1]	ND-5.8	ND-4.7
Chrysene	10	No Exceedance	ND-18	No Exceedance	No Exceedance
Benzo(b)flouranthene	1	No Exceedance	ND-20	ND-12	ND-6.7
Benzo(a)pyrene	0.7	No Exceedance	ND-22	ND-6.3	ND-4.5
Dibenzo(a,h)anthracene	0.7	No Exceedance	ND-3.8	No Exceedance	No Exceedance
Indeno(1,2,3-c,d)pyrene	1	No Exceedance	ND-13	ND-2.6	ND-2.1
Priority Pollutant Metals (mg/kg)					
Beryllium	0.8	No Exceedance	<0.59-1.2	No Exceedance	No Exceedance
Polychlorinated Biphenyls (mg/kg)	1	No Exceedance	No Exceedance	No Exceedance	No Exceedance
Pesticides (mg/kg)					
Dieldrin	0.04	No Exceedance	ND-2.1	ND-0.62	ND-3.1

1 Not Detectable to-19mg/kg

5.7.1.2 Centerfield Taxiway

The soil pre-characterization data indicate that soil underlying the proposed Centerfield Taxiway contains variable levels of contamination. The soil data indicate that no volatile compounds were present nor were any of the aliphatic fractions from the total petroleum hydrocarbon tests. The soil was found to exceed the S-2 Reportable Concentrations (RC S-2) for the polynuclear aromatic hydrocarbons, as determined in the EPH analysis. The PAH contamination was found from Taxiway Echo north to Taxiway Romeo. Beryllium was the only priority pollutant metal to exceed the RC S-2. This condition was found adjacent to Runway 15L/33R and between Taxiways Echo and Charlie. Lead in the soil was found to exceed the 100 mg/Kg TCLP trigger level by a slight amount (110 to 120 mg/kg) at three scattered locations. The results of the TCLP testing indicate that the soil did not exceed the TCLP regulatory limit of 5.0 mg/l for lead and is, therefore, not hazardous. The insecticide dieldrin was found in the soil at 8 locations. It is believed that the dieldrin originated from historical mosquito control programs. The soil was not found to contain polychlorinated biphenyls.

5.7.1.3 Taxiway November Realignment

Soil underlying the area for the realignment of proposed Taxiway November was found to be contaminated in excess of the Reportable Concentrations for S-2 soil with four polynuclear aromatic hydrocarbon (PAH) compounds, and the insecticide dieldrin. This contamination was only found in the surface soils (0-2 ft). The soil data indicate that no volatile compounds were present nor were any of the aliphatic fractions from the total petroleum hydrocarbon tests.

5.7.1.4 Southwest Corner Taxiway Reconfiguration

The soil sampling and analysis data indicate that the soil in the area of the proposed Southwest Corner Taxiway Reconfiguration contains concentrations of four PAH compounds and the insecticide dieldrin which exceed the Reportable Concentrations for S-2 soil. The soil data indicate that no volatile compounds were present nor were there any of the aliphatic fractions from the total petroleum hydrocarbon tests.

5.7.2 Governors Island Central Artery/Tunnel Materials Storage Site

Section 5.6.2 of the Airside Project Draft EIS/EIR presented an extensive discussion of the temporary Massachusetts Highway Department (MassHighway) Central Artery/Tunnel project soil stockpile at Governors Island. The discussion was included because at that time it appeared that a portion of the stockpiled materials would need to be relocated if unidirectional Runway 14/32 was to be constructed.

In 1999, Massport was approached by the Court-appointed Receiver of the Rubchinuk Landfill in Middleton, Massachusetts to assist in the closure of the landfill in accordance with a Landfill Closure Plan approved by the DEP. As a result of this request, in June 1999, Massport developed a third amendment to the 1993 Grant of Easement with MassHighway. This 1999 amendment facilitated a partial release (removal) of soil from Governors Island for transfer to the Rubchinuk Landfill. The first amendment to the Grant of Easement allowed Massport to use a portion of the area for storage and disposal of Massport soils from the Logan 2000 projects. A second amendment in 1996 allowed the MassHighway to use stockpiled materials for construction of the I-90 Airport Interchange at Logan. The 1999 amendment releases MassHighway from all of its right, title and interest to obligations from this "released area," totaling approximately 24.8 acres.

The removal of soil from the Governors Island release area was initiated in June, 1999 at a rate of approximately 1,400 tons/day (1,000 cubic yards). In total, 380,000 tons (approximately 240,000 cubic yards) of the MassHighway soil was removed from Governors Island by November 2000. As a result, no MassHighway soil will need to be removed from Governors Island for runway construction.

5.8 Other Environmental Categories

The FAA's Airport Environmental Handbook (5050.4A) requires that a range of issues be addressed in terms of potential environmental consequences. Several of these potential impact categories are not applicable to the Airside Project. Specific impact categories that are not relevant to the proposed Airside Project improvements are discussed below.

5.8.1 Coastal Barriers

There are no coastal barrier resources as defined by the Coastal Barrier Resources Act (PL97-348) in the project area. As such the project will not affect these resources.

5.8.2 Wild and Scenic Rivers

Logan Airport is not adjacent to, nor will it affect any body of water included in the Wild and Scenic Rivers System Inventory. Accordingly, the project will have no impact on a river subject to the Wild and Scenic Rivers Act (PL 90-542).

5.8.3 Farmland

Logan Airport does not include any areas of farmland and therefore the project will not result in the conversion of any farmland to nonagricultural purposes. The project is consistent with the Farmland Protection Act (PL 97-98).

5.8.4 Energy Supply and Natural Resources

The addition of runway and taxiway elements will necessitate a slight increase in airfield energy use, primarily for construction and permanent airfield navigational lighting and signage. There is adequate energy to meet the energy needs of these temporary and long-term demands.

5.8.5 Light Emissions

As noted above, implementation of the taxiway and or runway improvements will require the installation and operation of new ground-mounted airfield navigational lighting and new airfield signage. All lighting and signage will be consistent with current equipment and operations. Proposed Runway 14/32 will not require the installation of a light pier.

5.8.6 Solid Waste

The Airside Project improvements will not generate the need for additional solid waste collection, control or disposal other than that associated with construction. Section 6.8.1 describes construction impacts of the Preferred Alternative.

6 Environmental Consequences

Key Points

This chapter repeats much of the analysis presented in the Airside Improvements Planning Project Draft Environmental Impact Statement/Environmental Impact Report (Airside Project Draft EIR/EIS). It is focused primarily on the comparison between the Preferred Alternative (Alternative 1A) and the No Action Alternative (Alternative 4) for representative fleets: the 29M Low Fleet and the 37.5M High Fleet scenarios. These fleets were chosen because they reflect the full range of potential impacts, including the worst case in terms of noise.[1]

Recent trends at Logan Airport indicate an increased presence of regional jet aircraft in the fleet mix. In order to examine the potential impacts that these 30-70 seat jet aircraft may have on the operational and environmental analysis of the proposed airside improvements, an additional long-term 37.5 million annual air passenger scenario was developed for this Supplemental Draft Environmental Impact Statement/Final Environmental Impact Report (Supplemental DEIS/FEIR). This fleet scenario, referred to as the 37.5M High Regional Jet (RJ) Fleet, reflects a significantly higher percentage of regional jet aircraft and a lower percentage of non-jet operations than any of the prior fleet forecasts presented in the Airside Project Draft EIS/EIR.

To further clarify the impacted areas, the analysis is presented through Geographic Information System (GIS) mapping with a more detailed base map and a different scale than was presented in Chapter 6 of the Airside Project Draft EIS/EIR.

Chapter 6 of this Supplemental DEIS/FEIS also includes an in-depth discussion of Environmental Justice requirements and additional Environmental Justice analyses requested by the Massachusetts Secretary of Environmental Affairs. In response to the Federal Aviation Administration's (FAA's) direction following the Supplemental Draft EIS Panel (SDEIS Panel) process, a school day/school year contour[2] is also included for the 29M Low Fleet scenario. Finally, the presentation of the flight tracks has been expanded to show the tracks over a wider geographic area.

1 Appendices E and F contain a summary of environmental impacts for other fleets analyzed in the Airside Project Draft EIS/EIR.
2 Contour provided in Appendix E of this Supplemental DEIS/FEIR.

Noise Benefits

- The Preferred Alternative reduces noise exposure in the most highly affected communities around Logan Airport: Winthrop, parts of East Boston, and Revere. Depending on the fleet forecast, all three communities have residents exposed to Day-Night Sound Level (DNL) values of 70 dB and above. Under the 29M Low Fleet scenario, use of Runway 14/32 will remove approximately 180 people in these communities from areas exposed to noise above 75 dB DNL, and some 60 people from areas of 70 dB DNL and above. Under the 37.5M High forecast, 199 people in areas of above 75 dB DNL and 2,800 people in areas of 70 dB DNL and above will no longer be exposed to those high noise levels. These numbers represent 77 percent and 73 percent reductions, respectively, in the total population residing in the 70 dB DNL and above and the 75 dB and above noise contours.

- The reduction in exposure at the highest DNL values is achieved by redistributing aircraft onto other runways and increasing the number of over-water operations. This redistribution causes increases in exposure at lower DNL values. Under the 29M Low Fleet scenario, the Preferred Alternative is estimated to increase the number of people exposed to noise above 65 dB DNL by 378, 2 percent of the total population in that contour compared to the No Action Alternative. Under the 37.5M High Fleet scenario, the Preferred Alternative increases the number of people above 65 dB DNL by 508, a 4 percent increase.

- Under the 29 M Low Fleet scenario, no one residing in an area exposed to noise above 65 dB DNL is projected to experience a noise level increase greater than 1.5 dB due to the Preferred Alternative. Approximately 400 people in Winthrop will experience decreases in noise of more than 1.5 dB compared to the No Action Alternative.

- In addition to reducing noise exposure at the highest DNL levels, the Preferred Alternative allows for more flights over water rather than over populated areas, as well as a more balanced geographic distribution of jet operations. Under the 37.5M High Fleet scenario, the Preferred Alternative results in 41 percent of jets utilizing runways affecting communities north and south of the airport, compared to 91 percent for the No Action Alternative. The percentage of jets flying over the water increases significantly, from 6 percent in the No Action Alternative to 30 percent with the Preferred Alternative.

- The Preferred Alternative, with its unidirectional Runway 14/32 and Centerfield Taxiway, reduces delay and consequently the number of nighttime (10 PM to 7 AM) operations by approximately 5 percent compared to the No Action Alternative under the 29M Low Fleet scenario.

- The Preferred Alternative is even more effective at reducing delays under the 37.5M High Fleet forecast. As a result, in that scenario the number of nighttime operations is reduced by approximately 20 percent compared to the No Action Alternative.

- Under the 37.5M High RJ Fleet scenario, the Preferred Alternative also reduces noise in the most-highly exposed communities. Proposed Runway 14/32 removes an estimated 164 people from exposure to noise above a DNL of 75 dB, a reduction of 74 percent compared to the No Action Alternative. It also removes approximately 1,433 people from exposure to DNL levels above 70 dB.

- Under the 37.5M High RJ Fleet scenario, the reduction in the highest exposure levels achieved with the Preferred Alternative causes increases in exposure for 364 people at DNL values above 65 dB. This is a 3 percent increase compared to the No Action Alternative.
- Under the 37.5M High RJ Fleet scenario, the Preferred Alternative reduces the number of nighttime operations by 13 percent compared to the No Action Alternative.
- The Preferred Alternative generally reduces the noise from ground movements, lowering DNL levels due to taxi operations by a few tenths to as much as 3 dB at seven close-in monitoring locations.

Land Use and Social Impacts

- The Preferred Alternative will have no significant impacts on land uses adjacent to or in the immediate vicinity of Logan Airport. The only relocation required for construction of Runway 14/32 involves the tenants of Building 60 in the South Cargo Area. Massport will provide relocation assistance as required under applicable law to mitigate impacts to affected tenants.

Historic Resources

- Providing sound insulation for the few historic residential properties within the 65 dB DNL contour associated with the Preferred Alternative will be undertaken in accordance with historic building rehabilitation standards established by the Secretary of the Interior (36 CFR 800.5(b)).
- The FAA and the Massachusetts Historical Commission have concurred that the proposed project will have no adverse effect on significant historic properties (see Appendix H for a copy of the letter from the Massachusetts Historical Commission, December 21, 1999.)

Other Section 4(f) Resources

- The FAA found that implementation of the Preferred Alternative will neither incorporate land from a Section 4(f) resource, nor affect the normal activity or aesthetic value of a public park, recreation area or wildlife refuge.
- The Preferred Alternative does not add any new parklands within the 65 dB DNL contour. The Boston Harbor Islands are already within the No Action 65 dB DNL contour, while the Arnold Arboretum, Emerald Necklace and Franklin Park are well outside the 65 dB DNL contour and will not experience new noise impacts.

Air Quality Benefits

- Implementation of any of the Airside Project alternatives produces a reduction in emissions and an improvement in ambient air quality when compared to the No Action Alternative, due to improved airfield efficiency and shorter aircraft delay periods.

- None of the Alternatives will result in any violations of federal or state air quality standards.
- Due to improved airfield efficiency and shorter delay periods, the Preferred Alternative results in a reduction of air pollutant emissions when compared to the No Action Alternative.
- The Airside Improvements Planning Project does not require a Federal General Conformity determination for the purposes of air quality, because it will not exceed general conformity thresholds – therefore it is assumed to conform to the State Implementation Plan.

Biotic Communities

- By constructing the Centerfield Taxiway and the Taxiway Delta extension, approximately 37 acres of existing grassland will be converted to pavement, resulting in the loss of an area of Upland Sandpiper habitat. An on-site and off-site mitigation plan has been developed in consultation with the Massachusetts Natural Heritage and Endangered Species Program (NHESP) to mitigate impacts to the upland sandpiper consistent with aircraft safety.
- There are no significant impacts to terrestrial vegetation, wetlands or typical wildlife.

Water Quality

- Construction of Runway 14/32 and the Taxiway components (the Preferred Alternative) will create additional impervious surfaces at Logan Airport and will increase the peak rate of runoff from Logan Airport to Boston Harbor by approximately 3.8 percent. The combination of overland flow across grass areas and the large number of discharge locations helps to attenuate and disperse contaminants in the runoff, and therefore the general quality of runoff under the Preferred Alternative is expected to be similar to present runoff.
- Since the existing water quality in Boston Harbor will not be affected by the construction of the runway or taxiway improvements, there are no adverse water quality impacts that would result from the Preferred Alternative.

Soil Removal

- All soils removed from the site will be managed in accordance with State regulations and Massport policy to minimize impacts. Appropriate sediment and erosion controls will be employed during construction and disturbed soils will be revegetated.
- The Airside Project Draft EIS/EIR identified a potential need to remove soil materials stockpiled on Governors Island for construction of Runway 14/32. In response to a request from the Court-appointed receiver for the Rubchinuk Landfill, Massport arranged for the transport of the Massachusetts Highway Department (MassHighway) soils from Governors Island to the Rubchinuk Landfill in Middleton. This work has since occurred as part of a separate initiative. The transportation of the MassHighway soils began in June 1999 and was completed in November 2000, therefore none of these soils will need to be moved offsite for construction of Runway 14/32.

Environmental Justice

- There is no disproportionate high and adverse impact on minority and low-income populations caused by the Preferred Alternative. Adverse noise impacts of the Preferred Alternative are not predominately borne by a minority or low-income population. Only 21 percent of the population within the resulting 65 dB DNL is minority, compared to the Suffolk County population which is 38 percent minority. Less than 2 percent of the population within the 65 dB DNL contour has a household income of less than 150 percent of poverty level.
- The additional area within the 65 dB DNL contour associated with the Preferred Alternative includes a predominantly Hispanic neighborhood in Chelsea which is predicted to experience an increase of 0.6 dB or less under the near-term 29M Low Fleet, the worst case scenario based on total noise exposure. Under FAA standards, this change is not a significant adverse impact. Mitigation of the increased noise will be provided to the affected community in the form of residential sound insulation.

Construction

- Construction of the runway and taxiway improvement components of the Preferred Alternative will occur on the existing airfield. Construction will be managed to minimize noise, air and water pollution, and other impacts to the adjacent community.
- The total period for the phased construction of the runway and taxiway improvement components of the Preferred Alternative is approximately five years. Construction vehicles would access the airport on designated haul routes via the Ted Williams Tunnel or Route 1A, and thus would not impact local residential streets adjacent to Logan Airport .
- Construction traffic associated with the Preferred Alternative will be reduced significantly from the number of truck trips presented in the Airside Project Draft EIS / EIR as a result of the reduction of soil material to be moved off-site.

Irretrievable Commitment of Resources

- The Preferred Alternative causes no irretrievable commitment of natural resources. Construction of the runway and taxiway improvement components of the Preferred Alternative will consume fuel and result in the consumption of raw materials such as gravel, concrete and other materials required for the construction process.
- Measures will be implemented to mitigate both short- and long–term impacts on natural resources to the greatest extent practicable.

6.1 Introduction

This chapter of the Supplemental DEIS/FEIR focuses on the benefits and impacts of two Airside Project Improvements Alternatives – the No Action Alternative and the Preferred Alternative which includes all improvements except Peak Period Pricing. It includes a discussion of long-term impacts relating to airfield operations, as well as a description of shorter-term construction impacts.

The environmental consequences of the proposed Airside Project improvements were evaluated against a near-term demand level of 29 million annual passengers and long-term levels of 37.5 and 45 million passengers (referred to in this document as 29M, 37.5M, and 45M). These demand levels are expected in the years 2003, 2015, and 2024, respectively. At each passenger level, two different operations forecasts were developed. The High and Low Fleet scenarios, presented in the Airside Project Draft EIS/EIR, reflect differing aircraft fleet mix assumptions. The Low Fleets assume more large jet operations than non-jet operations, similar to current conditions. The High Fleets assume a greater proportion of non-jet aircraft and thus a higher level of total operations for the same passenger level.

Recent trends at Logan Airport indicate an increased presence of regional jet aircraft. In order to examine the potential impacts that these 30-70 seat jet aircraft may have on the operational and environmental analysis of the proposed airside improvements, an additional long-term 37.5 million passenger scenario was developed for this Supplemental DEIS/FEIR. This fleet scenario, referred to as the 37.5M High Regional Jet (RJ) Fleet, reflects a much higher percentage of regional jet aircraft and a lower percentage of non-jet operations than do any of the prior fleet forecasts presented in the Airside Project Draft EIS/EIR.

The Supplemental DEIS/FEIR includes updated operational and environmental analyses of 1998 conditions similar to that contained in the 1998 Annual Update prepared in October 1999. While the 1999 Environmental Status and Planning Report (ESPR, formerly the GEIR) published in December 2000 includes updated analyses for 1999, the differences between the two study years are small. Between 1998 and 1999, operations declined by 2.5 percent, primarily due to a reduction in regional carrier operations. Since the fleet mix and runway use varied little, the noise contours and population impacts were also similar, with slightly less impact in Winthrop and Boston and slightly more in Chelsea and Revere in 1999 compared to 1998. The air quality and other environmental analyses also yielded similar results. Since the relevant comparison for evaluating the proposed airside improvements is the comparison between the No Action and Preferred Alternatives, and since 1998 and 1999 are similar in terms of passengers, operations, and environmental impacts, this Supplemental DEIS/FEIR maintains the 1998 modeling analysis as a representation of recent conditions at Logan Airport.

The Supplemental DEIS/FEIR focuses on the 29M Low and 37.5 High Fleet scenarios, because these represent the full range of environmental impacts, as well as the newly added 37.5 M High Regional Jet fleet scenario. Appendices E and F contain a summary of environmental impacts for other fleets analyzed in the Airside Project Draft EIS/EIR.

Specific studies and analyses conducted to assess the environmental consequences in this Supplemental DEIS/FEIR include:

- Review of potential benefits and impacts of each Alternative, but with a focused comparison of the Preferred Alternative (all actions except Peak Period Pricing) to the No Action Alternative for the 29 M Low and 37.5M High Fleet scenarios.
- Environmental analyses associated with an additional future fleet scenario – the 37.5M High RJ Fleet scenario.
- Inclusion of GIS mapping with a more detailed base map for noise contours showing land use at a larger scale.
- Tabular and graphic comparison of the Preferred Alternative and No Action Alternative showing the number and location of people who are exposed to noise.
- Discussion of the relationship between the noise analyses conducted for the Airside Project and the Runway 27 EIS.
- Focused noise contour analysis comparing the *1998 Annual Update*, Runway 27 EIS, and the Airside Project noise contours.
- Reevaluation of construction impacts (truck trips and air quality) associated with construction of Runway 14/32 due to the reduced amount of soil materials that will need to be removed from Governors Island.
- Expanded discussion of environmental justice and related mitigation.
- A school day/school year contour for the 29M Low Fleet scenario which results in the largest noise-exposed area (See Appendix E).

6.2 Noise

This section presents the results of the noise modeling analysis of the Airside Project Alternatives, focusing on the Preferred Alternative and comparing its noise impact with the No Action Alternative under two different aircraft fleet assumptions.

The smaller fleet assumes a demand level of 29 million passengers and a lower percentage of non-jet operations (29M Low Fleet scenario). It is forecast to occur in the year 2003. The second fleet scenario assumes a demand level of 37.5 million passengers and a higher percentage of non-jet operations (37.5M High Fleet scenario). This is the long-term outlook, and is forecast to occur around 2015. As described in Chapter 4, a third fleet, the 37.5M High Fleet Regional Jet scenario (37.5MHigh RJ Fleet) has been added in this Supplemental DEIS/FEIR. It reflects replacement of many non-jet commuter operations by small 30-70 seat regional jets, such as the Canadair Regional Jet and the Embraer 145. These fleets were described in detail in Chapter 4, and together they bracket a range of potential exposure levels. Noise impacts of other fleets were analyzed in Section 6.2 of the

Airside Project Draft EIS/EIR. Summary noise results for the other fleets are contained in Appendix E of this Supplemental DEIS/FEIR.

This section also addresses the exposure levels associated with the Preferred Alternative and the No Action Alternative in the context of the noise that occurred in 1998 due to actual operations that year. It discusses DNL noise contours and other metrics common to all three scenarios, and presents population counts under each Alternative as determined by the Integrated Noise Model (INM). To address noise exposure caused by aircraft taxiing between runway and apron areas, this section also summarizes findings from the Airside Project Draft EIS/EIR pertaining to noise from taxiway and other ground operations. See Section 5.2 of the Airside Project Draft EIS/EIR for a description of the noise models used in these analyses and Section 6.2 of the Airside Project Draft EIS/EIR for additional information on the effects of ground noise under action alternatives other than the Preferred Alternative.

Finally, the noise section concludes with an evaluation of all Airside Project alternatives using the new 37.5M High RJ Fleet scenario described in Chapter 4.

6.2.1 INM Inputs for the Evaluation of Flight Noise

6.2.1.1 Fleet Mix and Operations

Operation summaries for 1998 and for the No Action and Preferred Alternatives under each of the future fleet forecasts are presented in Table 6.2-1. Summaries based on the 1993 Historic Modeled condition were presented in the Airside Project Draft EIS/EIR. Modeled activity includes both scheduled and unscheduled operations by major air carriers, commuter airlines, and air cargo operators, as well as general aviation jet and turboprop aircraft.

The Preferred Alternative has no effect on the total number of flights in and out of Logan Airport -- air carriers and cargo operators will schedule their aircraft to meet the public's travel and shipping needs. However, there *are* important noise implications between the No Action and Preferred Alternatives in the manner that these flights are accommodated. Some runway and taxiway configurations have lower capacities than others, and when those combinations have to be used because of poor weather or other circumstances, aircraft delays grow rapidly. The effect of aircraft delays on noise exposure is twofold:

- As delays increase, daytime and evening flights slip into nighttime hours, causing greater noise disturbance and an increase in thosenoise measures (DNL, LeqN, and TAN, in particular) that are sensitive to late night activity; and
- Use of low capacity runway configurations makes achieving the Preferential Runway Advisory System (PRAS) goals more difficult for air traffic controllers.

The Preferred Alternative, which includes unidirectional Runway 14/32 and the Centerfield Taxiway, is estimated to reduce the number of nighttime operations from approximately 132 to 125, a decrease of 7 operations per night or 5 percent of the projected nighttime operations that would otherwise occur under the No Action Alternative for the 29M Low Fleet scenario.

Table 6.2-1
Average Daily Operations for 1998 and for Future 29M Low and 37.5M High Fleet Scenarios for the No Action Alternative and the Preferred Alternative

	Stage 2 Jets	Stage 3 Jets	Turboprops	Totals		
Fleet Forecast	**Day/Night**	**Day/Night**	**Day/Night**	**Day**	**Night**	**Daily**
1998 Actual	90/6	572/100	590/38	1,252	144	1,396
29M Low Fleet						
No Action (Alt. 4)	16/6	699/114	550/13	1,265	132	1,397
Preferred (Alt.1A)	16/5	703/108	553/12	1,272	125	1,397
37.5M High Fleet						
No Action (Alt. 4)	0/0	819/209	615/22	1,434	231	1,665
Preferred (Alt.1A)	0/0	843/166	635/18	1,478	184	1,662

Note: "Day" is defined as 7:00 AM to 10:00 PM and "Night" is defined as 10:00 PM to 7:00 AM, consistent with the definitions as used in DNL calculations.

For the long-term 37.5M High Fleet scenario, the difference is even more significant. The Preferred Alternative reduces the number of nighttime jet operations by an estimated 43 per night and the number of nighttime turboprops by another four, for a total reduction in nighttime flights of 47, or about 20 percent compared to the No Action Alternative, all as a result of fewer delays.

The significant reduction in nighttime operations under the Preferred Alternative is enhanced by the fact that overall noise exposure is expected to decrease further in the near future. Both the 1998 fleet as well as the 29M Low Fleet scenario include several noisy Stage 2 jets with maximum takeoff weights greater than 75,000 pounds. However, beginning January 1, 2000, every aircraft at Logan greater than 75,000 pounds met FAR Part 36 Stage 3 noise limits. Furthermore, many of the Stage 2 jets that have been hushkitted to meet Stage 3 requirements are expected to be retired over the next ten years and replaced with newer and quieter Stage 3 aircraft. The number of Stage 2 aircraft in the 29M Low Fleet scenario is insignificant.

Some operators at Logan Airport have already announced and implemented plans for fleet renewals. As indicated in the *1998 Annual Update*, the US Airways and Delta Shuttles planned to replace 78 daily operations flown in hushkitted Boeing 727-200s. These aircraft meet Massport's as well as the FAA's noise regulations, but Massport lobbied the carriers to update their fleets to newer and quieter aircraft. Since those discussions, the Delta Shuttle replaced its 727 aircraft with new, quieter 737-800 aircraft, and US Airways took delivery of new Airbus 320s to replace its older 727s. These fleet improvements and the reductions in night operations with the Preferred Alternative will each contribute to meaningful reductions in noise exposure.

6.2.1.2 Flight Tracks

Flight tracks were developed for Runway 14/32 with input from the FAA in order to evaluate noise impacts for both Alternative 1 and the Preferred Alternative. These tracks are shown in Figures 6.2-1 through 6.2-4. They indicate that all arrivals to unidirectional Runway 14/32 come from the harbor over water and that all departures climb out in the opposite direction over the water. While aircraft that use Runway 14/32 do fly over land, they are considered over-water flight paths because they cross land further from the runway and at higher altitudes than operations to or from other Logan Airport runways.

In Figure 6.2-1, jet arrivals to Runway 32 coming into the area from the north and west approach Logan Airport on a downwind leg well east of the airport together in the same flow of traffic with other jet arrivals to Runway 33L, then make a right turn crossing over to a final approach that is over the harbor and parallel to the approach for Runway 33L. Propeller aircraft from the north and west (see Figure 6.2-2) are separated from the flow of jet traffic well northwest of Logan Airport and fly south over the Airport making a left turn to join the final approach to Runway 32. Both types of aircraft coming into the area from southerly directions approach the airport and make a left turn (as is done now) to line up on their final approaches over the harbor.

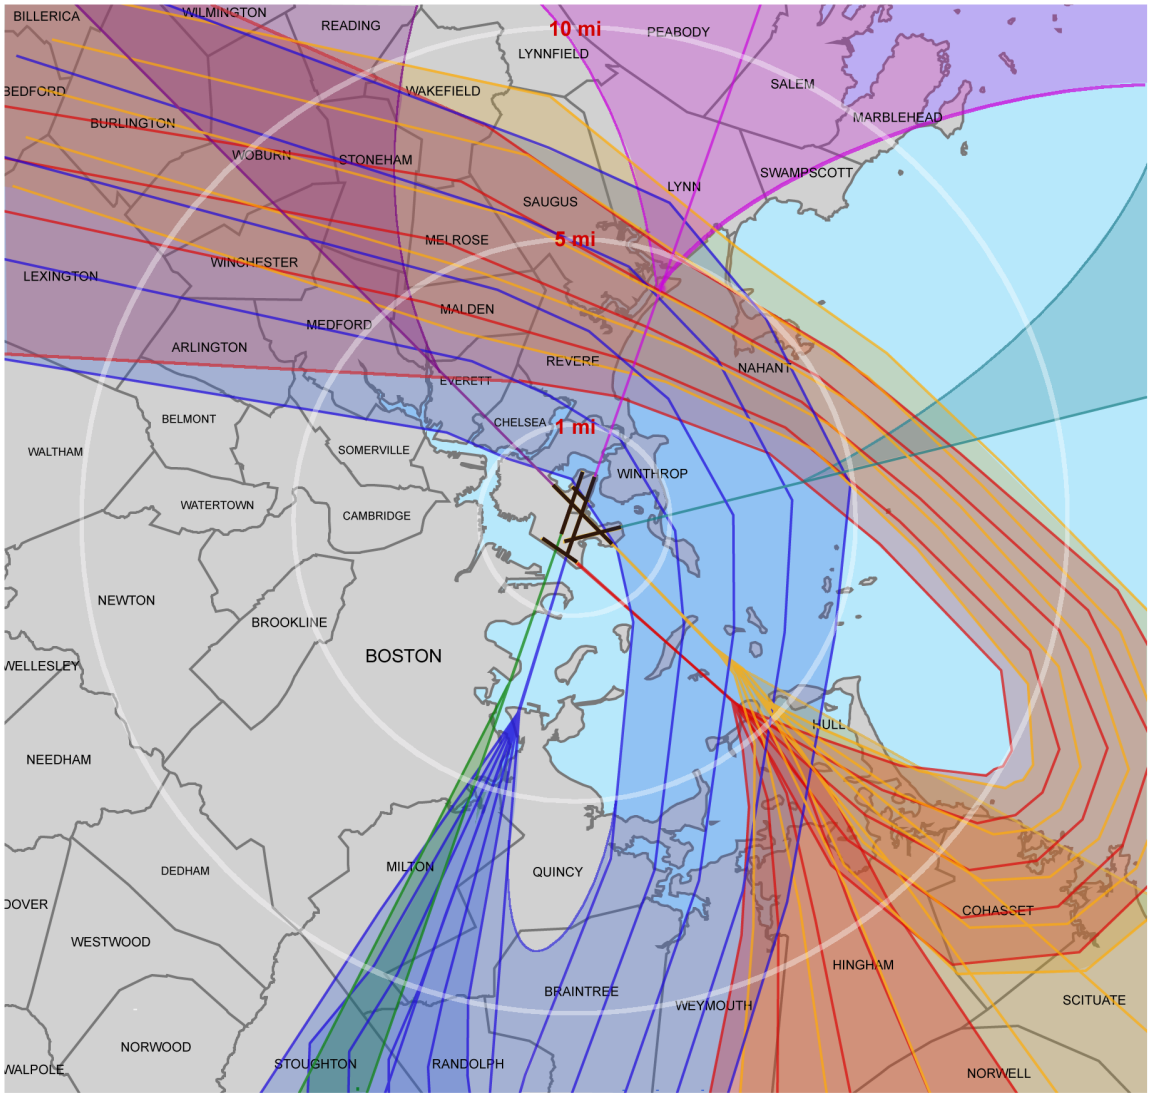
The closest populated land area overflown by arrivals to Runway 32 is tip of the Hull peninsula, approximately 5 miles from the runway end. In contrast, arrivals to Runways 4L/R and 22L/R fly over populated land areas until they are within one mile of the runway ends. In the case of departing aircraft, Figures 6.2-3 and 6.2-4 show jet aircraft turning to a heading that takes them out of the harbor over water, similar to the current jet departure procedure for Runway 15R. Most of these jet aircraft do not cross back over land until they are at or above 6,000 feet .The propeller aircraft climb initially over the water and then are vectored within the indicated zone by ATC towards their enroute headings.

For the lowest-altitude portions of flights to and from the proposed runway, aircraft are flying over water. In addition, the flight tracks for the runway demonstrate that aircraft using Runway 14/32 will fly over cities or towns that are currently overflown by aircraft utilizing Logan Airport 's existing runways.

6.2.1.3 Runway Use

Summaries of effective runway use projections for the Preferred and No Action Alternatives under both the 29M Low Fleet and the 37.5M High Fleet scenarios are shown in Tables 6.2-2 and 6.2-3 below. [3](See Appendix H of the Airside Project Draft EIS/EIR for jet runway usage for the 29M High Fleet, 37.5M Low Fleet, and 45M High Fleet scenarios.) Effective jet utilizations for 1998 operations appeared in Table 5-12 of the *1998 Annual Update* and are reproduced here in Table 6.2-4 for reference along with the corresponding PRAS goals discussed in Chapter 4.

3 Effective operations include jet operations, only with nighttime operations weighted by a factor of 10. Thus one nighttime operation is equivalent to 10 daytime jet operations.



Aircraft Altitude Along the Flight Path (from runway touchdown)

1 Mile from Touchdown = 500 ft. or Less 5 Miles from Touchdown = 2,000 ft. or Less 10 Miles from Touchdown = 3,000 ft. or Less

27	21.7%	16.6%	21.7%	17.9%
33L	28.6%	5.2%	42.3%	11.9%
Totals	100.1%	100.1%	100.0%	100.0%

Because of random variations in wind and weather conditions, as well as fluctuations in demand, it is unlikely that the annual PRAS goals will ever be achieved exactly. However, comparing 1998 conditions with the stated goals, there are several areas where improved compliance would help reduce noise in the most highly exposed neighborhoods. Use of Runway 9 for departures is currently more than double the desired utilization and directly contributes to high exposure levels in Winthrop. Also, lower-than-desired use of Runway 15R for departures and 33L for arrivals means that more noise is occurring over populated areas rather than over water to the southeast of Logan Airport.

Over use of Runways 4L and 4R for arrivals creates higher noise exposure in the vicinity of City Point in South Boston and other South Shore communities. In addition, excessive use of Runway 22L for arrivals and 4R for departures creates more noise for areas of Winthrop and Bayswater Street in East Boston. Each of these situations is exacerbated further under the 37.5M High Fleet scenario.

Only portions of East Boston and Chelsea have benefited from this current use; Runway 33L is used for departures less than half as much as its PRAS goal, and Runway 15R is used for arrivals only one-seventh as much as its PRAS utilization goal.

Under the 29M Low Fleet scenario, the Preferred Alternative, which includes Runway 14/32, offers a dramatic improvement in Air Traffic Control's (ATC's) ability to achieve the PRAS goals compared to the No Action Alternative. For example, under the 29M Low Fleet scenario effective use of Runway 9 for departures over Winthrop decreases from 30 percent in 1998 and 28 percent in the future No Action Alternative down to approximately 18 percent with the Preferred Alternative; the PRAS goal for Runway 9 is 13 percent. Similarly, to the south, effective utilization of Runways 4L and 4R for landings over City Point decreases from 37 percent in 1998 and 35 percent in the future No Action Alternative to 25 percent with the Preferred Alternative. The PRAS goal for those runways is 21 percent.

The Preferred Alternative also increases the use of overwater flight paths. Under the 29M Low Fleet scenario, departures on Runway 15R increase from 13 percent with the No Action Alternative up to 18 percent (Runways 15R and 14) with the Preferred Alternative, consistent with the PRAS objective to maximize over-water routings. In the opposite

direction, arrivals to Runway 33L increase from 33 percent with the No Action Alternative up to 37 percent with the Preferred Alternative (Runways 33L and 32).

Collectively, these changes clearly show that the added flexibility of the new Runway 14/32 plays a significant role in ATC's ability to better achieve the current PRAS goals, especially those that involve over-water operations. The resulting noise benefits are discussed in the following section.

6.2.2 INM Modeled In-flight Noise Levels

As the discussion in the prior sections indicates, with a growing number of operations at Logan represented by the 29M Low Fleet scenario and 37.5M High Fleet scenario, the No Action Alternative will cause Runways 4L/R and 27to be utilized for increasing numbers of arrivals and Runways 22L/R and 9 for increasing numbers of departures. These increases will occur despite the fact that even present runway usages exceed the PRAS goals. Without the addition of Runway 14/32, these runway combinations are the only ones that can accommodate the increasing demand. Noise exposure off these runway ends will increase, as well.

Unidirectional Runway 14/32, on the other hand, will give air traffic controllers two or three runways to use during northwest winds (instead of the current one or two), and will offer greater flexibility to achieve both long-term annual PRAS goals and short-term dwell and persistence relief. This benefits the neighborhoods experiencing the most aircraft noise, accomplishing exactly what PRAS was designed to do.

The next sections document the noise contour results of the INM modeling for the No Action and Preferred Alternatives.

6.2. 3 Area-wide Cumulative Noise Exposure Contours

Appendix L of the Airside Project Draft EIS/EIR presented a complete set of DNL contours covering the full range of project Alternatives and fleet forecasts addressed in this study. A summary of the noise results for fleets analyzed in the Airside Project Draft EIS/EIR is in Appendix E of this Supplemental DEIS/FEIR. The 65 dB DNL contours for the No Action and Preferred Alternatives under the 29M Low and 37.5M High Fleets are presented in Figures 6.2-5 and 6.2-6 to show the relative effects of each of the study cases on an improved base map. Figures 6.2-7 and 6.2-8 compare DNL contour values of 60, 65, and 70 dB under each of the two fleet assumptions. Their differences are discussed in the following section.

6.2.3.1 Comparison of The No Action Alternative and the Preferred Alternative

29M Low Fleet Scenario

Figure 6.2-7 compares the DNL contours for the Preferred Alternative with the No Action Alternative for the near-term 29M Low Fleet. In general, the No Action Alternative produces more delay and poorer compliance with PRAS goals.

With the addition of Runway 14/32, noise exposure decreases off the approach end of Runway 4R in the City Point area of South Boston but only at lower levels of exposure between DNL 60 dB and 65 dB; no one in this area is exposed to noise above a DNL of 65 dB. To the southwest, consistent with achievement of PRAS goals, departure noise from Runway 27 increases with the addition of Runway 14/32, adding to the exposure in that area of South Boston both in the increment from DNL 65 dB to 70 dB and also further to the southwest in the increment from 60 to 65 dB, though the increases are less than 1.5 dB in both areas. Exposure due to takeoffs over East Boston and Chelsea is relatively unchanged under the Preferred Alternative given that there are only minor differences in runway use between the No Action and Preferred Alternative, and aircraft departing from Runway 33L generally make 15 degree left turns up the Mystic River. However, in those neighborhoods directly aligned with Runway 33L/15R there are small increases in exposure of less than 1.5 dB due to increases in arriving air traffic on Runway 15R.

Exposure in Revere is very slightly reduced, while the remaining areas of Winthrop, near and on Point Shirley, experience decreased exposure due to decreased use of Runway 9 for departures. Increased use of both Runway 15R and the new Runway 14 for departures, combined with their added use in the opposite direction for landings (to Runways 33L and 32) , will cause increased exposure over Long Island and other Boston Harbor Islands, generally in the range of DNL 60 dB to 65 dB. Noise exposure further to the southeast in Hull is expected to be less than DNL 60 dB.

37.5M High Fleet Scenario

Under the long-term 37.5M High Fleet, the above noise exposure patterns are more pronounced, as seen in Figure 6.2-8. Exposure in South Boston, east of D Street, which is affected by departures from Runway 27, increases approximately 5 dB DNL. Increased departures on Runway 33L and increased arrivals on Runway 15R produce approximately 4 dB DNL higher exposure in portions of East Boston and Chelsea. For other communities surrounding Logan noise exposure declines by 2 to 3 dB DNL under the Preferred Alternative.

The Harbor Islands will generally receive increases in DNL from 3 to 5 dB due to better achievement of the PRAS goals for departures on Runway 15R and arrivals on Runway 33L.

6.3.2.2 Comparison of 1998 Actual Exposure with the 29M Low No Action Alternative

To give additional context, Figure 6.2-9 compares the 60, 65, and 70 dB DNL contours for the 29 M Low Fleet scenario with 1998 exposure levels. The 29M Low Fleet scenario is used in this discussion because it most closely resembles current activity levels at Logan Airport.

Differences between the two cases occur in several areas– the 1998 contours are larger than the 29M Low Fleet No Action contours over much of Winthrop (including Point Shirley) and in South Boston off of Runway 27. Conversely, in East Boston and Chelsea off the departure end of Runway 33L, the 1998 contours are smaller than the 29M Low Fleet No Action Alternative. There are three basic reasons for these differences.

The 1998 contours are generally larger than those for the 29M Low Fleet scenario because the latter has fewer Stage 2 aircraft, including 17 percent fewer at night (see Table 6.2-1). Thate smaller number accounts for a 3 to 4 dB improvement in average exposure around the entire airport when compared to 1998. A reduction of similar magnitude was anticipated in the *Logan Airport 1998 Annual Update*, where Figure 5-8 depicted the anticipated improvement in exposure off of Runway 27 if *no* Stage 2 aircraft were to remain in the 1998 fleet. Based on this analysis, the fact that fleet differences exist between 1998 and the No Action Alternative should not imply that the 29M Low Fleet scenario is inaccurate or unrepresentative of the future. The No Action Alternative is based on passenger demand that exceeds 1998 levels by only 2.5 million people, and it assumes a higher use of Stage 3 aircraft than occurred in 1998. The 29M Low Fleet represents an upper bound on near-term noise exposure since all US aircraft with maximum gross takeoff weights greater than 75,000 pounds must comply with Stage 3 criteria as of January 1, 2000.

Another important difference between the 1998 and the No Action Alternative noise contours pertains to the departure corridor for Runway 27. The 1998 corridor is based on a large sample of radar data taken from Massport's noise monitoring system after the FAA implemented a new jet departure procedure in accordance with the FAA Record of Decision (ROD) on the Runway 27 EIS. The Airside Draft EIS/EIR, however, was under way well before the ROD, and could only approximate how the new departure procedure would be specified by the FAA. The difference in model inputs creates a slight clockwise (westward) shift to the contours off of Runway 27 for each of the Airside Project Alternatives compared to 1998. It does not represent a real difference in corridor location or noise between the two scenarios. It does, however, contribute to the large difference in population counts between 1998 and the 29M Low No Action Alternative in South Boston.

A third cause for differences in the noise contours is due to variations in assumed runway utilization. For valid statistical modeling purposes the Airside Project alternatives utilize 10-year weather data and corresponding runway assignments. Since weather patterns have a major effect on runway use, and since weather varies substantially from year to year, modeled results will invariably differ from any actual year.

In sum, the fleet, flight track, and runway assignment differences all help explain the differences in noise contours shown in Figure 6.2-9.

6.2.4 Area-wide Cumulative Noise Exposed Population

Estimates of the number of people residing within various 5 dB increments of noise exposure for the 29M Low Fleet and 37.5M High Fleet scenarios under the No Action and Preferred Alternatives are summarized in Table 6.2-5. Included in this table are the 1998 populations for reference (population summaries for the 29M High Fleet, 37.5M Low Fleet, and 45M High Fleet scenarios are found in Appendix L of the Airside Project Draft EIS/EIR and Appendix E of this Supplemental DEIS/FEIR). It is notable that under all of the improvement alternatives, the population exposed to each value of DNL (greater than or equal to 60 through 75 dB) is significantly less than that of either the 1993 modeled historical or the 1998 actual noise-exposed populations. This improvement is due to the January 1, 2000 phase-out of the noisier Stage 2 aircraft having a maximum gross takeoff weight greater than 75,000 pounds.

Table 6.2-5
Summary of Noise-Exposed Population

Day-Night Sound Level in dB	1998 Actual	No Action Alternative (Alt. 4)	Preferred Alternative (Alt. 1A)	Preferred Alt. Compared to No Action	Percent Change *re* No Action
29M Low Fleet					
DNL 75 dB and above	577	257	77	-180	-70%
DNL 70 dB and above	2,679	1,521	1,459	-62	-4%
DNL 65 dB and above	23,296	17,531	17,909	378	2%
DNL 60 dB and above	93,860	59,523	60,418	895	2%
37.5M High Fleet					
DNL 75 dB and above	577	257	58	-199	-77%
DNL 70 dB and above	2,679	3,828	1,028	-2,800	-73%
DNL 65 dB and above	23,296	11,499	12,007	508	4%
DNL 60 dB and above	93,860	41,659	52,153	10,494	25%

1 Except for 1998, all estimates are based on runway use chosen to most nearly achieve PRAS goals and reflect the effects of delayed aircraft as determined by the DELAYSIM model.

2 References to 29M Low Fleet and 37.5M High Fleet scenarios do not apply to 1993 or 1998; they are applicable only to The Preferred and No Action Alternatives.

3 Where applicable, counts now include 502 institutional residents of Long Island in Boston Harbor. None of these individuals is exposed to noise greater than DNL of 65 dB under any of the study scenarios; they do, however, experience DNL values of 60 to 65 dB in some cases but were not previously counted in the Airside Project Draft EIS/EIR or the Logan Airport GEIR and its Annual Updates.

As shown in Table 6.2-5, the Preferred Alternative significantly reduces the population exposed to DNL values greater than or equal to 70 and 75 dB. The benefits range from 70 to 77 percent for exposures greater than or equal to 75 dB, and from 4 to 73 percent for values of 70 dB and more. These reductions are a direct result of the implementation of Runway 14/32, which enables FAA controllers to better achieve PRAS goals that were specifically designed to give relief to the populations experiencing the most airport noise.

These benefits at high exposure levels cause increases in population within the 65 dB contour for the Preferred Alternative; they range from 2 to 4 percent, while increases within the 60 dB DNL contour range from 1 to 25 percent.

Noise exposed populations are broken down by community area in Tables 6.2-6 and 6.2-7. The first presents the exposed populations for the 29M Low Fleet scenario while Table 6.2-7 presents similar data for the 37.5M High Fleet scenario. At a DNL of 70 dB or greater, the most heavily affected communities are East Boston and Winthrop. Revere becomes heavily affected at these exposure levels with the higher fleet forecast. At 65 dB or greater, Chelsea and South Boston are added to the list of impacted communities (similar tables for the other fleets were in Appendix L of the Airside Project Draft EIS/EIR, and are summarized in Appendix E of this Supplemental DEIS/FEIR).

An analysis of the neighborhoods exposed to noise levels greater than or equal to 70 dB indicates that Runway 14/32 is projected to reduce impacts for those areas most affected by airport noise. For example, under the No Action Alternative for the 29M Low Fleet scenario, approximately 200 residents of Point Shirley are projected to reside within the 75 dB DNL contour; however, under the Preferred Alternative, 60 percent, or about 120 Point Shirley residents, would benefit from a reduction in noise sufficiently large to remove them from the 75 dB DNL contour. In addition, a total of approximately 860 residents of Point Shirley are exposed to noise above a DNL of 70 dB if no action is taken; this number is reduced to about 675 with the Preferred Alternative. Still larger numbers of Point Shirley residents benefit from the Preferred Alternative at lower DNL levels. In addition, East Boston's Orient Heights neighborhood is projected to experience a small reduction in population within the 75 and 70 dB contours with the Preferred Alternative compared to the No Action Alternative. These reductions are the result of the additional flexibility available to air traffic controllers in the selection of runways and hence a greater ability to achieve PRAS long-term and short-term noise goals.

1. "Boston (Other)" includes Back Bay, Dorchester, Jamaica Plain, Roxbury, and the South End.
2. Except for 1998, all estimates are based on runway use chosen to most nearly achieve PRAS goals and reflect the effects of delayed aircraft as determined by the DELAYSIM model.
3. References to 29M Low and 37.5M High Fleets do not apply to 1998; they are applicable only to Alternatives 1A and 4.

In the 37.5M High Fleet scenario, greater benefits are realized. Approximately 100 more residents of Winthrop located along Court Road plus more than 2,000 residents of Revere and nearly 200 people in Orient Heights are no longer included in the highest exposure levels. In fact in this scenario, some 2,800 people would no longer be exposed to DNL levels above 70 dB if Runway 14/32 were constructed and used as projected. The tradeoff for this improvement is that a net of some 500 people (approximately 4 percent of the total noise-exposed population around Logan Airport) have their exposure increased to DNL 65 dB.

6.2.4.1 Population Experiencing Significant Shifts in Noise Exposure

FAA Criteria

The FAA standards for assessing changes in noise-exposed populations center around two factors: the absolute levels of noise which residents experience and the magnitude of the change to which they are exposed. In particular, both FAA Order 1050.1D entitled *Policies and Procedures for Considering Environmental Impacts* and FAA Order 5050.4A entitled *Airport Environmental Handbook* indicate that changes in DNL of 1.5 dB or more are considered significant when DNL values are greater than 65 dB. Further, if there are populated areas above 65 dB DNL where the project-related noise does change by more than 1.5 dB, then areas between 60 dB DNL and 65 dB DNL are also examined to determine if there are any residential areas where the project–related noise changes by more than 3.0 dB. This analysis must be conducted for all reasonably foreseeable scenarios, which for this Supplemental DEIS/FEIR are considered to be the No Action and Preferred Alternatives for the near-term 29M Low Fleet scenario. The 37.5M High Fleet and the 37.5M High RJ Fleet which are considered later in this chapter are considered to be longer-term forecasts and are more speculative in nature.

Table 6.2-8 summarizes the numbers of people who meet these criteria for assessing noise exposure for the No Action and the Preferred Alternatives under the 29M Low Fleet scenario. The table is divided into two sections – the top half addresses the segment of population that becomes newly included within the specified criteria under the Preferred Alternative; the bottom half summarizes those people whose noise exposure declines as a result of the Preferred Alternative. A zero indicates that no one will experience a change of the magnitude specified if the Preferred Alternative is implemented.

Secretary of the Office of Environmental Affairs Request under MEPA

In addition to standard FAA impact criteria used to judge this project, the May 7, 1999 EOEA Certificate on the Airside Project Draft EIS/EIR requested that the Final EIR report on the number of people located within the 60 to 65 dB DNL whose noise exposure had changed by 1.5 dB or more. Table 6.2-9 reports these counts.

Table 6.2-9

This analysis shows that the Preferred Alternative reduces the number of people exposed to high noise levels in portions of Winthrop, East Boston and Revere. To achieve these reductions, the noise is redistributed more in line with the PRAS goals causing increased noise at lower exposure levels in the communities of Chelsea, East Boston (near the departure end of Runway 33L), and South Boston.

6.2.5 Other Indicators of Changed Exposure

Besides population counts, other metrics such as computed noise levels at specific points also are used to identify changes in aircraft noise. In these analyses, the selected points coincide with 21 of Massport's permanent noise monitoring locations along with two temporary measurement sites that were used to collect additional data for the Airside Project. These sites and respective analyses are presented in Chapter 5 of the Airside Project Draft EIS/EIR. They have been updated to show results for 1998 actual operations where available. The five additional metrics reported at each site are:

- Day-Night Sound Level (DNL)
- Nighttime (10:00 PM to 7:00 AM) Equivalent Sound Level (LeqN)
- Maximum Sound Level (Lmax)
- Time-Above 55, 65, 75, 85, and 95 dBA during Nighttime hours (TAN), and
- Time-Above 55, 65, 75, 85, and 95 dBA for full 24 hour periods (TA24).

6.2.5.1 Day Night Sound Levels (DNL)

The calculations of DNL by noise monitoring location for the 29M Low Fleet scenario and the 37.5M High Fleet scenario are presented in Table 6.2-10 and Table 6.2-11, respectively. Similar tables for all other study fleets were contained in Appendix L of the Airside Project Draft EIS/EIR. The future year noise is less than that in 1998 at most locations and both Alternatives, reflecting the replacement of Stage 2 aircraft with quieter Stage 3 aircraft.

At the bottom of Tables 6.2-10 and 6.2-11, average changes in noise level for the 29M Low Fleet and 37.5M High Fleet scenarios are compared for different exposure levels. The Preferred Alternative, which includes Runway 14/32, shows the greatest reduction in DNL when compared to the No Action Alternative under the 37.5M High Fleet scenario. At three of the four close-in sites where projected DNL levels exceed 70 dB under the No Action Alternative for the 29M Low Fleet scenario, the Preferred Alternative reduces exposure levels by 0.1 to 0.9 dB. Under the 37.5M High Fleet scenario, the Preferred Alternative decreases noise at sites above 70 dB by 1.4 dB to 2.2 dB. (See Table 6-2.14 in the Airside Project Draft EIS/EIR for comparisons to other alternatives). The differences in the DNL between the Preferred Alternative and the No Action Alternative are principally the result of the airfield improvements that affect the Air Traffic Control Tower's ability to achieve PRAS recommendations.

6.4.5.2 Nighttime Equivalent Sound Level (LeqN)

Table 6.2-12 presents the calculations of nighttime equivalent sound level (LeqN) for the 29M Low Fleet scenario. The LeqN is lower than DNL because the number of nighttime operations is much smaller than the number of daytime operations and because there is no 10dB nighttime penalty as in the DNL. The change in (LeqN) ranges from an increase of 3.2 dB to a decrease of 3.1 dB, with sites overall averaging a decrease of 0.1 dB for the Preferred Alternative compared to the No Action Alternative. Similar LeqN tables for other fleets, including the 37.5M High Fleet scenario, are contained in Appendix L of the Airside Project Draft EIS/EIR.

6.2.5.4 Maximum Sound Level (Lmax)

Table 6.2-13 compares the maximum sound level (Lmax) of the Preferred Alternative to the Lmax of the No Action Alternative for the 29M Low Fleet and 37.5M High Fleet scenarios. These values are for the aircraft operation that has the highest Lmax, whereas the values in the previous tables were for the cumulative noise exposure for all aircraft operations. In Table 6.2-13, the same aircraft operation is usually responsible for the highest value of Lmax in each fleet for all Alternatives, even though the number of its operations varies among the Alternatives. The values of Lmax in the 37.5M High Fleet scenario are generally less than those in the 29M Low Fleet scenario, primarily because of differences in the scheduled air carrier aircraft types – some Stage 2 aircraft that appear in the lower fleet forecast have been replaced with quieter Stage 3 aircraft in the longer-termforecast. These Lmax values are not as useful for assessing the relative noise among various locations and fleets as are the cumulative metrics such as DNL because they represent extreme values, rather than typical values, and because they do not consider how often the noise events occur. Similar Lmax tables for all fleets are contained in Appendix L of the Airside Project Draft EIS/EIR.

6.2.5.5 Time-Above 24-Hour (TA24)

Table 6.2-14 shows the 24-hour time-above (TA24) calculated for threshold values of 55 dB to 95 dB for the Preferred Alternative and the No Action Alternative under the 29M Low Fleet scenario. Comparison of these TA24 data show that the Preferred Alternative reduces the time-above various thresholds at most locations by about 20 to 40 percent. Maximum values of TA24for the No Action Alternative are found at locations 4 (Bayview and Grandview) and 7 (Loring Road near Court Road in Winthrop) which have 2 and 1 minutes above 95 dB, and 17 and 11 minutes above 85 dB, respectively. These two locations also have the highest DNL values. The other locations that have more than one minute per day above 85 dB have DNL values of 69 to 70 dB.

6.2.5.6 Time-Above Night (TAN)

Table 6.2-15 presents the corresponding time-above data for the nine hour nighttime period (TAN). These time-above values are much smaller than those for the entire 24- hour day because of the shorter time period and the reduction in the level of aircraft operations.

Table 6.2-12
Comparisons of INM-Computed Nighttime Equivalent Sound Levels (LeqN) from Flight Operations for the 29M Low Fleet Scenario

Noise Monitor	Location	No Action Alternative	Preferred Alternative	Change (in dB) No Action - Preferred

6.2.6 Ground Taxi Noise Levels

Aircraft ground taxi noise was assessed in the Airside Project Draft EIS / Final EIR at seven noise monitoring stations (NMS) in the immediate vicinity of the airport. The analysis looked at five metrics, and a summary of those analyses is provided in this Supplemental DEIS / FEIR.

- Day-Night Sound Level (DNL)
- Night (10:00 PM to 7:00 AM) Equivalent Sound Level (LeqN)
- Maximum Sound Level (Lmax)
- Night Time-Above 55, 65, 75, 85, and 95 dB (TAN)
- 24-hour Day Time-Above 55, 65, 75, 85, and 95 dB (TA24)

Ground noise was calculated for Alternatives 1, 2, 3 and 4. The ground noise for Alternatives 1 and 1A will be similar for fleets where the effective runway utilization is the same for both Alternatives. The effective runway utilization data for arrivals (Table 6.2-3 in the Airside Project Draft EIS / EIR) and departures (Table 6.2-4 in the Airside Project Draft EIS / EIR) indicates little difference between Alternatives 1 and 1A for the 29M Low and High Fleet scenarios, and the 37.5M Low Fleet scenario. Therefore, the results of the Alternative 1 ground noise analysis for these fleets also apply to the Preferred Alternative.

The noise from ground taxi operations is significantly less than the noise from in-flight operations, which includes the noise from both takeoff ground roll and application of thrust reverser on landing. For example, the in-flight DNL for average propagation in South Boston at Farragut and 2nd (Location E) is 40 to 44 dB greater than that of ground taxi noise, and for maximum propagation it is 23 to 27 dB greater. At the other six locations, the in-flight DNL for average propagation is 17 to 30 dB greater than that of the ground taxi noise, and for maximum propagation is 2 to 13 dB greater.

Implementation of the Preferred Alternative would produce a modest reduction in ground taxi noise for the Bayswater section of East Boston and Winthrop (NMS #7, 10 and 12), located to the northeast of the airport, particularly as operations increase and greater congestion occurs on the existing taxiway. These are the locations most affected by ground taxi noise, and their average reductions in DNL range from 1.9 to 3.3 dB. (See Table 6.2-16) There are smaller reductions at Somerset and Johnson (NMS # 6) in Winthrop (0.8 to 1.0 dB) and at the two positions (Location A and NMS #14) in Jeffries Point (0.1 to 0.3 dB). There is a small increase for average propagation (0.8 dB) and a decrease for maximum propagation (1.6 dB) at Farragut and 2nd (Location E). However, at this location in South Boston, the ground taxi operations would often be inaudible.

Table 6.2-16
Change in DNL Values from Ground Operations, by Noise Monitoring Site

Average Change dB	-3.3	-2.4	-1.9	-0.8	-0.3	-0.2	-1.6

6.2.6.1 Other Ground Taxi Noise Levels

Ground taxi noise was also calculated for four other noise metrics: Nighttime Equivalent Sound Level (LeqN), Maximum Sound Level (Lmax), Night Time-Above a Noise Threshold (TAN), and 24-hour Day Time-Above a Noise Threshold (TA24). Tables for all locations and all fleet scenarios are contained in Appendix L of the Airside Project Draft EIS/EIR.

The Nighttime Equivalent Sound Level (LeqN) calculated for ground taxi operations are about 7 to 10 dB lower than the DNL values because there are fewer operations per hour in the nighttime period and the 10 dB penalty for nighttime operations in the DNL metric is not applied to LeqN. For all future scenarios, the Preferred Alternative results in an average reduction of 0.5 to 0.6 dB in LeqN when compared to the No Action Alternative. The Maximum A-weighted Sound Levels (Lmax) calculated for the ground taxi operations are identical at 59 dB for average propagation and 75 dB for maximum propagation. This means that for almost all of the cases, the same aircraft type and operation at the same location produced the recorded Lmax value.

Tables 6.2-17 and 6.2-18 present the time-above threshold values in minutes for ground taxi noise at NMS # 12 for nighttime and 24-hour day, respectively. Data are presented for three thresholds, 55, 65, and 75 dB. Note that total time-above 75 dB values less than 0.5 minute are rounded down to 0 minutes. The nighttime values of TA in Table 6.2-17 are much smaller than those in Table 6.2-18 for a 24-hour day, and are roughly in proportion to their respective numbers of operations.

The reductions in 24-hour time-above at the East Boston Yacht Club (NMS#12) for the Preferred Alternative are relatively dramatic. The average decrease in TA24 for maximum

propagation is 43 percent for TA24 55 dB and 55 percent for TA24 65 dB. At Loring Road near Court Road, Winthrop (NMS # 7) the corresponding decreases are 65 and 54 percent for TA24 55 and 65 dB, respectively, and at Bayswater and Shawsheen, East Boston (NMS #10) the decreases for TA24 55 and 65 dB are 53 and 27 percent, respectively. These differences in TA24 for the Preferred Alternative are of the same nature as those found above in reviewing the DNL metric at these locations.

6.2.7 37.5M High Regional Jet Fleet

6.2.7.1 Fleet Mix and Operations

A summary of operations under each of the five project alternatives considered is provided in Table 6.2-19 . Daytime and nighttime operations for jets, turboprops and total aircraft

and are compared to 1998 actual operations. Activity is comprised of scheduled and unscheduled operations by major air carriers, commuter airlines, and air cargo operators; it also includes general aviation jet and turboprop aircraft.

Alternatives that incorporate peak period pricing (Alternatives 1, 2, and 3) have fewer operations than the No Action and Preferred Alternative, but the differences in activity levels are small, and have a negligible effect on noise exposure since most cancelled operations are smaller, quieter aircraft. The most significant factor affecting the noise impacts of different alternatives is the amount of delay that occurs when accommodating the scheduled flights:

- As delays increase, more operations slip into nighttime hours, causing greater disturbance and an increase in those measures of noise (DNL, LeqN, and TAN) that are sensitive to late night activity; and
- High delays limit controller flexibility and make it difficult to achieve PRAS goals.

Alternatives incorporating Runway 14/32 (Alternative 1 and the Preferred Alternative 1A) significantly reduce nighttime operations by reducing delays. Thus, the Preferred Alternative results in approximately 37 fewer nighttime operations (a reduction of nearly 13 percent compared to the No Action Alternative); 32 of those are in jet aircraft. Alternative 1 results in some cancellations and reduces the delays even further, causing the number of nighttime operations to decrease by 57 compared to the No Action Alternative; 48 of those are in jet aircraft.

A second factor affecting the noise impacts of the 37.5M High RJ Fleet is the noise of the individual aircraft themselves. Though the mix of aircraft types varies, the primary difference between the 37.5M High RJ Fleet and previous forecasts is the higher number of 30- to 70-seat regional jet aircraft that are entering the fleet and replacing many of the existing and previously forecast turboprop operations. For example, in the 37.5M High Fleet, only about 26 of the 1,665 daily operations were by regional jets while 637 operations were by turboprops; in the 37.5M High RJ scenario, regional jets account for 395 operations of 1,601 daily operations while turboprops account for only 217.

Table 6.2-19
Average Daily Operations for 37.5M High RJ Fleet (All Alternatives)

	Stage 2 Jets	Stage 3 Jets	Turboprops	Totals		
Fleet Forecast	Day/Night	Day/Night	Day/Night	Day	Night	Daily
37.5M High RJ Fleet						
No Action (Alt. 4)	0/0	1,125/259	188/29	1,313	288	1,601
Preferred (Alt.1A)	0/0	1,157/227	193/24	1,350	251	1,601
All Actions (Alt. 1)	0/0	1,143/211	179/21	1,322	231	1,553
No 14/32 (Alts. 2/3)	0/0	1,117/236	175/25	1,292	261	1,553

Note: "Day" defined as 7:00 AM to 10:00 PM and "Night" defined as 10:00 PM to 7:00 AM, consistent with the definitions as used in DNL calculations.

This shift to a higher proportion of regional jet operations does not imply increased noise. A 50-seat Embraer 145 regional jet is actually 5 to 10 decibels quieter, both on takeoff and on landing, than even some of the most recently manufactured Stage 3 jet aircraft, and though it is louder than some turboprops, it is quieter than many other turboprop types currently operating at Logan Airport. Thus, the increased presence of regional jets is more likely to impact noise exposure through runway use and delay impacts rather than through the fleet mix difference itself. The impacts of these fleet changes on the noise environment will be described in more detail later in this section.

6.2.7.2 Flight Tracks and Runway Use

Flight tracks for the new 37.5M High RJ Fleet scenario were assumed to be identical to the tracks modeled under other fleets as shown earlier in Figure 6.2-1 through Figure 6.2-4. The figures indicate arrivals to Runway 32 converge and descend to the runway over Boston Harbor while departures from Runway 14 climb out in the opposite direction over the harbor.

Summaries of runway use for this 37.5M High RJ Fleet are presented in Section 4.7. Each of these tables allows a comparison of the number of operations expected to overfly a given community for each of the study alternatives.

6.2.7.3 INM Modeled In-Flight Noise Levels

Consistent with other fleet forecasts in this Airside Improvements Planning Project, the 37.5M High RJ Fleet further illustrates that with a growing number of operations, the No Action Alternative will result in increased use of Runways 4L/R, 22R, and 27 for arrivals and Runways 22L/R, 4L/R, and 9 for departures. These increases are anticipated despite the fact that current runway usages exceed PRAS goals and indicate a need to shift traffic to other runways. Controllers continue to need these north/south runway combinations because they have the highest capacity of any configurations available and that capacity is needed more frequently as demand increases. Noise exposure off these runway ends can therefore be expected to increase as well under the No Action Alternative.

Similar to the conclusions drawn from other fleet forecasts, with implementation of the Preferred Alternative under the 37.5M High RJ Fleet, air traffic controllers would have use of two or three runways during northwest winds (instead of the current one or two), and have greater flexibility and opportunity to achieve PRAS goals for both long-term annual runway use and short-term dwell and persistence relief. This benefits the communities presently experiencing the most aircraft noise.

Noise contours generated by the INM for all of the 37.5M High RJ Fleet Alternatives (4, 1A, 1, and 2/3) are shown in Figures 6.2-10 through 6.2-14. The exposure attributable to each Alternative is depicted by the 60, 65, and 70 dB DNL contours. The No Action Alternative is presented first to establish a basis for comparison; it is followed by the Preferred Alternative and then a comparison of the key 65 dB DNL contours for the Preferred and No Action Alternatives to show differences in the areas of significant noise impact. The final two figures present contours for the other Alternatives. Alternatives 2 and 3 have identical in-flight noise exposure since they differ only in that Alternative 2 includes the taxiway improvements. They are therefore portrayed by the same set of contours and population results.

6.2.7.4 Differences in Noise Exposure for Alternatives 4, 1A, 1, and 2/3 Under the 37.5M High RJ Fleet

Figure 6.2-10 shows the DNL contours for the No Action Alternative (Alternative 4) and indicates a continuing dependence on the north/south runway combinations. The 65 dB DNL contour for this scenario extends as further north along the Revere shoreline and south to Squantum than any Alternative. It is also the largest of the Alternatives over most of Winthrop. Conversely, to the west it remains close to the Airport off of Runway 27, never extending beyond the Inner Harbor, and stays close to the end of Runway 33L, extending to about Chelsea Street in East Boston.

The Preferred Alternative with its addition of unidirectional Runway 14/32 in Figure 6.2-11, shifts this balance by reducing coverage of the 65 dB DNL contour in Revere, Winthrop and South Boston near City Point. This shift in runway use results in increased exposure above 65 dB, primarily in commercial areas of South Boston near the World Trade Center, to the northwest in the Eagle Hill area of East Boston, and beyond to approximately Broadway in Chelsea.

A comparison of the No Action and Preferred Alternatives in Figure 6.2-12 indicates a 1 to 2 dB DNL decrease in exposure attributable to the Preferred Alternative in parts of Revere and Winthrop that receive exposure levels in excess of 70 dB DNL. These improvements are achieved through the greater flexibility afforded by the additional runway, permitting air traffic controllers to reduce the activity on the north/south runway combinations and shift operations so that arrivals increase to Runways 33L and 32, largely over Boston Harbor, or so that departures increase on Runways 27 and 33L. This causes increased noise on the order of 4 to 5 dB off of those runway ends, but at levels below those experienced in Winthrop and Revere.

Figure 6.2-13 depicts contours for Alternative 1. This scenario presumes construction of unidirectional Runway 14/32 but also includes the effects of peak period pricing. The differences compared to the Preferred Alternative are relatively small, causing both increases as well as decreases in exposure, generally less than a decibel in magnitude. Small additional benefits from peak period pricing occur in Revere and Winthrop at contour levels above 70 dB DNL, while areas of South Boston off the approach end of 22R also receive small improvements compared to the Preferred Alternative but at lower DNL levels of 65 to 70 dB. Negligible differences between the two scenarios occur in other areas of South Boston affected by departures from Runway 27, but small increase in exposure occurs to the northwest off of Runway 33L causing increased exposure in parts of East Boston and Chelsea.

The contours for Alternatives 2 and 3 are shown in Figure 6.2-14. Except for a small improvement in Winthrop and a small reduction in noise in South Boston near the approach end of Runway 22L, the contours generally differ very little from the No Action Alternative.

6.2.7.6 Population Affected by Noise

Estimates of the number of people residing within 5 dB increments of noise exposure for each of the alternatives examined under the 37.5M High RJ Fleet are summarized in Table 6.2-20. Also included are the 1998 populations for reference. Table 6.2-21, which follows, summarizes a comparison of the Preferred Alternative with No Action and indicates the improvement that occurs at the highest exposure levels as a result of the increased flexibility afforded by Runway 14/32.

Table 6.2-20
Summary of Noise-Exposed Population for All Alternatives – 37.5M High RJ Fleet Scenario

Day-Night Sound Level in dB	1998 Actual	No Action Alternative (Alt. 4)	Preferred Alternative (Alt. 1A)	With Peak PeriodPricing (Alt. 1)	Other Improvements (Alts.2/3)
High Regional Jet Fleet					
DNL 75 dB and above	577	222	58	58	135
DNL 70 dB and above	2,679	3,700	2,267	2,020	3,584
DNL 65 dB and above	23,296	11,493	11,857	12,470	11,223
DNL 60 dB and above	93,860	36,857	50,048	48,332	36,024

1 Except for 1998, all estimates are based on runway use chosen to most nearly achieve PRAS goals and reflect the effects of delayed aircraft as determined by the DELAYSIM model.

Table 6.2-21
Comparison of Noise-Exposed Population for the No Action and Preferred Alternatives – 37.5M High RJ Fleet Scenario

Day-Night Sound Level in dB	1998 Actual	No Action Alternative (Alt. 4)	Preferred Alternative (Alt. 1A)	Preferred Alt. Compared to No Action	Percent Change from No Action to Preferred Alt
High Regional Jet Fleet					
DNL 75 dB and above	577	222	58	-164	-74%
DNL 70 dB and above	2,679	3,700	2,267	-1,433	-39%
DNL 65 dB and above	23,296	11,493	11,857	364	3%
DNL 60 dB and above	93,860	36,857	50,048	13,191	36%

1 Except for 1998, all estimates are based on runway use chosen to most nearly achieve PRAS goals and reflect the effects of delayed aircraft as determined by the DELAYSIM model.

Comparing these figures for the No Action and Preferred Alternatives, the Preferred Alternative again provides important reductions in population exposure to DNL values greater than or equal to 70 and 75 dB with a minimal increase in numbers of people exposed above 65 dB DNL. Only at exposure levels between 60 and 65 dB DNL is there a significant increase in population exposed to noise from the Preferred Alternative.

These reductions are a direct result of the implementation of Runway 14/32, which enables the Air Traffic Control Tower to better achieve PRAS goals which were specifically designed to give relief to the populations experiencing the most aircraft noise.

The results in the previous two tables are broken down by community area in Tables 6.2-22 and 6.2-23 below. Similar tables for the other fleets are in Appendix L of the Airside Project Draft EIS/EIR.

6.2.7.7 Other Indications of Changed Exposure Using the 37.5M High RJ Fleet

As discussed in Section 6.2.5, five other metrics were computed at specific points to identify changes in aircraft noise. The selected points coincide with 21 of Massport's permanent noise monitoring locations along with two additional sites selected for the Airside Project.

The calculations of DNL for the No Action and Preferred Alternatives under the 37.5M High RJ Fleet are presented and compared in Table 6.2-24. Results for the other alternatives under the High RJ Fleet are presented in Appendix E of this document. Similar tables for all other study fleets are contained in Appendix L of the Airside Project Draft EIS/EIR.

Even under the No Action Alternative, the 37.5M High RJ noise is less than that in 1998 at the majority of locations around the airport, largely reflecting the air carriers' replacement of Stage 2 aircraft with quieter Stage 3 aircraft at the end of 1999 in compliance with Federal regulations.

Those sites that are shown to increase above 1998 levels under the No Action Alternative are limited to six locations (9, 16 and 17 to the north in East Boston and Revere, and 3, 23, and 24 to the south in South Boston, Dorchester, and Milton. As shown in Figure 5.2-4 in Chapter 5, all of them are directly aligned with Runways 4L/R and 22L/R and reflect the increased need to use those runways ever more frequently as demand increases. This result is further illustrated graphically by comparing the 1998 DNL noise contours of Figure 5.2-3 with the DNL contours for the 37.5M High RJ No Action Alternative shown in Figure 6.2-10.

Comparing the Preferred and No Action Alternatives in the table above, it is notable that the same six locations just mentioned are expected to experience decreases in DNL of 1.4 to 1.8 dB if the Preferred Alternative is implemented. In addition, significant decreases of 1.5 to 2.4 dB are seen at sites 9 and 12 on Bayswater Street and at the yacht club in East Boston and at sites 4 and 7 in Winthrop, which along with site 16 in Revere, are now or will be exposed to DNL levels above 70 dB – the highest of any locations in the vicinity of the Airport – if no action is taken.

25	Squaw Rock Park, Quincy	51.2	49.9	48.4	-1.5
26	Hull High School, Hull	58.1	53.3	55.7	2.4
E	Farragut @ 2nd, South Boston	N/A	68.1	66.3	-1.8
Average change from 70 dB and above Between Alts 4 and 1A (5 Sites)					**-1.9**
Average change from 65 dB and above Between Alts 4 and 1A (10 Sites)					**-1.7**
Average change from all values Between Alts 4 and 1A (23 Sites)					**0.1**

Balanced against these improvements are significant increases in exposure at Site 2 in South Boston off of Runway 27 and Sites 13 and 15 in East Boston and Chelsea off of Runway 33L where noise is expected to increase 4.5 to 4.9 dB, although none of these specific sites is projected to experience DNL values in excess of 65 dB with the Preferred Alternative under this fleet assumption. A smaller increase of 2.4 dB is also expected at Hull High School, but at a DNL value of 55.7 dB, this is well below any criteria for significant impact.

Table 6.2-25 presents INM calculations of nighttime equivalent sound levels (LeqN)at specific points, reflecting the differences in exposure occurring during the hours from 10:00 PM to 7:00 AM. Appendix E presents similar calculations for the other alternatives under the 37.5M High RJ Fleet.

Nighttime equivalent sound levels show generally similar patterns of change between the No Action and Preferred Alternatives. The highest nighttime exposure levels of 65 dB and above occur at Sites 4 and 7 in Winthrop, Site 9 on Bayswater Street in East Boston, and Site 16 in Revere. Each of these locations is expected to experience decreases in nighttime noise of 1.3 to 2.1 dB if the Preferred Alternative is implemented. At three other Sites (3, 5, and 12) in South Boston, Winthrop and East Boston where nighttime exposure is lower but still above 60 dB, decreases in nighttime exposure of 1.7 to 2.3 dB are expected under the Preferred Alternative.

Balanced against these reductions in nighttime noise are increases in LeqN ranging from 3.6 to 4.3 dB at sites 1, 2, 13, 15, and E, though none of these locations is expected to have nighttime noise increase above 57.9 dB with the Preferred Alternative, and two of the sites (1 and E in the South End and on Farragut Street in South Boston) are expected to have increases to less than 50 dB.

Finally, Table 6.2-26 compares INM-computed maximum sound levels for the No Action and Preferred Alternatives at the specific points. For these and all other Alternatives, there are no expected differences between cases because the same aircraft operation is responsible for the highest level and neither the aircraft type nor the location of the operation changes from one Alternative to the next.

The one remaining supplemental noise metric, Time Above Threshold sound levels for both 24-hour and for nighttime hours, is reported in Appendix E for all 37.5M High RJ Alternatives.

In conclusion, the major findings regarding the study Alternatives and their relative impacts on community noise levels are supported by the evaluation of the High RJ Fleet and are generally consistent across all fleets examined in this study. The improved noise levels achieved through the added flexibility in use of runways afforded by the new unidirectional Runway 14/32 will reduce noise exposure in the most highly impacted areas still remaining around Logan Airport. Areas of Winthrop, East Boston (north of the airport), and Revere are all currently exposed or are expected to be exposed to DNL levels above 70 dB, with areas of Winthrop and East Boston experiencing levels above 75 dB even now. These can be reduced on the order of several decibels by the redistribution of traffic onto other runways in accordance with PRAS goals, though the redistribution will cause increased noise between DNL values of 65 and 70 dB in East Boston and Chelsea and cause increased noise from 60 to 65 dB in parts of South Boston.

6.3 Land Use and Social Impacts

Under the Federal Aviation Administration's (FAA) National Environmental Policy Act (NEPA) directives, land use compatibility is typically associated with the extent of the airport's noise impacts. The noise analysis described in Section 6.2 has determined that the Preferred Alternative actually reduces the number of people in the most highly exposed areas around the Airport (DNL 75 and above as well as DNL 70 and above) compared to the No Action Alternative, and it causes only a minimal increase in the numbers (2 to 4 percent) of people exposed to DNL values above 65 dB. In addition, with better achievement of PRAS goals, the analysis indicates that the Preferred Alternative reduces the numbers of people in all high exposure increments compared to 1998 actual conditions. Sound insulation will be installed to mitigate for noise impacts (an increased number of people within the 65 dB DNL noise contour) resulting from the Preferred Alternative.

All proposed Airside Project Alternatives involve operational and/or construction improvements to reduce delay at Boston-Logan Airport. The noise analysis indicates that the Preferred Alternative will allow Logan Airport to more closely meet the established PRAS goals. The runway and taxiway components for the Preferred Alternative would be constructed on the existing airfield. The only relocation required for construction of Runway 14/32 is for the tenants of Building 60 in the South Cargo Area of the airport. The tenant of Building 61, the U.S. Postal Service, plans to vacate the building independently of the Airside Project. (See Section 6.3.4.1 for more detail.) The project is restricted to activities and purposes compatible with normal airport operations. As described in more detail below, it is compatible with existing land use plans and will not hamper redevelopment efforts in surrounding communities.

Based on the land use compatibility criteria outlined in FAA NEPA regulations, the Airside Project Alternatives with mitigation will have no impact on land uses adjacent to or in the immediate vicinity of the airport.

6.3.1 Consistency with Local Land Use Plans

This section discusses land use compatibility with respect to zoning of adjacent areas in East Boston, and presents a discussion of the South Boston waterfront area in response to the May 7, 1999 EOEA Certificate and applicable federal requirements.

6.3.1.1 East Boston

As a state entity, Massport is not subject to local zoning regulations in the performance of its essential governmental functions. All the Airside Project alternatives are nonetheless consistent with the proposed East Boston Neighborhood District Zoning Article (Article 53), which includes establishment of the Logan International Airport Subdistrict (LIA). The airport site is located within the LIA which has a stated purpose "to accommodate those uses necessary to the operation of an international airport while ensuring that land uses and development associated with operations of the airport are confined to the airport boundary and that such uses do not impose adverse impacts in other areas of the East Boston Neighborhood Plan, developed with the extensive

participation of the East Boston Planning and Zoning Advisory Committee, civic associations, business groups, and residents."

6.3.1.2 South Boston

The section of South Boston along the Fort Point Channel and Inner Harbor is known as the South Boston Waterfront District, and has historically been used for industrial use. However, new developments such as the Federal Courthouse, Seaport Hotel and future Boston Convention Center suggest a future mix of land uses in the district. The City of Boston has developed *The Seaport Public Realm Plan*[4] (the Plan) for the South Boston Waterfront District that contains land use and design guidelines on future development of this area. The proposed distribution of land uses emphasizes the creation of mixed use neighborhoods and public open space within the Fort Point Channel and Piers Districts, with the Reserved Channel District to the east of D Street remaining industrial. The Plan has taken into account FAA's requirements for safe runway operation in the recommendation of allowable building height in the Seaport District.

Under the Preferred Alternative, the arrival and departure paths for aircraft using Runway 14/32 will be over water in Boston Harbor. (See Figures 6.2-1 and 6.2-2 in Section 6.2) Runway 14/32 is being designed, and would be used, for unidirectional use only. All arrivals would be over Boston Harbor to the 32 approach end and all departures would be from the 14 end, heading out over the harbor. Therefore there will be no conflict with future development along the South Boston waterfront as a result of the construction of unidirectional Runway 14/32, or any of the other physical improvements under the Preferred Alternative.

6.3.2 Historic Resources Context

6.3.2.1 Section 4(f) Resources (Historic)

An assessment of impacts to cultural resources was conducted for the Preferred Alternative. There are no parklands, historic properties or sites, or other Section 4(f) resources on the airfield in the area of the proposed runway and taxiway improvements. Therefore, there are no significant adverse impacts Section 4(f) resources from the implementation of the Preferred Alternative. In addition, the Preferred Alternative will not substantially impair the historic integrity of any historic site or district. The Massachusetts Historical Commission (MHC) has concurred that the Preferred Alternative will have no adverse effect on significant historic properties (MHC letter to FAA, December 21, 1999, Appendix H). Therefore, the FAA has concluded that Section 4(f) is not applicable. See Section 6.3.3 for an additional discussion of parklands.

4 Boston Redevelopment Authority, *The Seaport Public Realm Plan*, dated February 1999.

6.3.2.2 Section 106 Historic Resources

An assessment of impacts to cultural resources was conducted for the Preferred Alternative. There are no historic properties on the airfield in the area of the proposed runway and taxiway improvements. Therefore, there are no direct impacts to historic properties from the implementation of the Preferred Alternative.

The analysis of potential indirect impacts associated with the Preferred Alternative was performed by comparing the 65 dB DNL contour for the No Action Alternative and the Preferred Alternative for the 29M Low Fleet scenario. Historic properties were identified in those areas where the 65 dB DNL contour for the Preferred Alternative extended beyond the 65 dB DNL contour for the No Action Alternative.

The FAA evaluated airport noise and land use compatibility in accordance with land use guidelines expressed in Federal Aviation Regulation (FAR) Part 150, Airport Noise Compatibility Planning (14 CFR 150). FAR Part 150 does not include guidelines specific to historic sites; however, the identified historic properties are comprised of commercial, manufacturing, and residential land uses, for which guidance is provided. In addition, general guidance within FAR Part 150 indicates that noise levels typically do not affect the relevant characteristics of urban historic districts (for example, their architectural features and recognition of their place in history). Moreover, when dealing with an existing airport (such as Logan Airport) within an urban setting (such as metropolitan Boston), any change in operating conditions aimed at more equitably distributing noise impacts (here, in accordance with the PRAS goals) may result in some increase in noise at specific historic sites while at the same time decreasing noise at other historic sites. As noted above, such impacts will not change the relevant characteristics (e.g., architectural features, historical significance) of such sites.

6.3.2.3 Indirect Impacts on Historic Properties

A description of historic properties identified within the net increased noise contour associated with the Preferred Alternative and a summary of potential impacts and mitigation are provided below (see Figures 6.3-1 to 6.3-3).

Saint Andrew Road, Boston/East Boston

St. Andrew Road is a three-block area (#54-154 St. Andrew Road) between St. Edward Road and Annavoy Street (see Figure 6.3-1), which is recognized for its high level of historic and architectural intactness and unity of scale. The neighborhood exhibits a street plan and sense of proportion, which are geographically and developmentally distinct when compared to the rest of East Boston. The growth of this neighborhood began in 1911, when the East Boston Company began to develop and sell off the lots, and continued to the mid-1930s. St. Andrew Road, surveyed in 1990, was recommended for inclusion in a proposed Bayswater National Register District.

Figure 6.3-3

Cultural Resources - Chelsea

The majority of this residential district is currently within the 65 dB DNL contour associated with current Logan Airport operating conditions. A small portion of St. Andrew Road located between St. Edward Road and Shawsheen Road would be affected by the net increase in the 65 dB DNL contour associated with the Preferred Alternative.

Boston Army Supply, Boston/South Boston

The Boston Army Supply Base area is roughly 43 acres and encompasses 29 individual buildings, and one major structure, Drydock #3 (see Figure 6.3-2). The former Army base is built on land created as part of a gradual filling process in South Boston, which began in 1836 and continued to the mid-twentieth century. Construction of the base began in 1918 as part of a massive federal building campaign at East Coast ports to handle supplies for World War I. The facility underwent three subsequent building phases, including one associated with World War II. The base is significant as a surviving, planned, military-industrial complex which was a key factor in the early-twentieth-century attempts to revitalize the Port of Boston, and notable for the immense scale of its early reinforced-concrete structures. The complex was surveyed in 1997 and recommended for inclusion in the National Register of Historic Places. This site is now being redeveloped as the Boston Marine Industrial Park.

The net increase in the 65 dB DNL contour associated with the Preferred Alternative would affect a narrow strip of the Boston Army Supply Base area, comprising approximately six commercial and industrial buildings.

C Street Area, Boston/South Boston

The C Street Area in South Boston is a roughly rectangular district, characterized by well-preserved reinforced concrete and masonry buildings, averaging in height from three to nine stories (see Figure 6.3-2). The area contains a cluster of early-twentieth-century industrial warehouses of varying embellishment associated with the height of Boston's wool trade. The area was surveyed in 1997 and four individual buildings were noted to meet National Register eligibility criteria, specifically 401, 415, and 425 Summer Street and 80 Fargo Street. This area is now largely being redeveloped as the Boston Convention and Exhibition Center.

The C Street Area would be affected by the net increase in the 65 dB DNL contour associated with the Preferred Alternative; however, the four commercial buildings meeting National Register criteria eligibility within the area do not fall within the increased noise contour.

Bellingham Square Historic District, Chelsea

The public, commercial, and residential buildings of the Bellingham Square Historic District are typical of an early twentieth-century commercial and civic urban center. Developed within a short time period following the Great Fire of 1908, the area, shown on Figure 6.3-3, reflects a strong degree of architectural homogeneity, possessing integrity of design through similar scale, massing, and setting. The district is also historically significant for its use of city planning concepts, which controlled construction following the 1908 fire. The district was listed in the National Register of Historic Places in 1985.

A small section of this district to the east of Congress Avenue would be affected by the net increase in the 65 dB DNL contour associated with the Preferred Alternative.

Downtown Chelsea Residential Historic District, Chelsea

The Downtown Chelsea Residential Historic District, listed on the National Register in 1988, is a visually cohesive group of buildings located in a primarily residential section of the City's downtown area, as shown on Figure 6.3-3. The residential district historically complemented commercial development in Chelsea Square to the west, industrial activity along the riverfront to the south, and the City's institutional focus at Bellingham Square to the northeast. Many of the district's residences were built on speculation, initially to meet the needs of a rapidly expanding population, and later to meet the housing needs of a City devastated by the Great Fire of 1908.
A narrow strip of this district in the area of Congress Avenue would be affected by the net increase in the 65 dB DNL contour associated with the Preferred Alternative.

Winthrop: 45 Enfield Road, 240 Pleasant Street, 73 & 77 Somerset Avenue, 88 Somerset Avenue, and 94 Somerset Avenue

Five properties in Winthrop that are included in the Inventory of Historic and Archaeological Assets of the Commonwealth fall within the 65 dB DNL noise contour, as shown on Figure 6.3-1. Two of the properties have been recommended for inclusion in the National Register: 240 Pleasant Street, built in the late 1860s, is architecturally significant as the most stylish and substantial towered villa in town; and 94 Somerset Avenue is historically significant as the most intact of all the houses associated with Winthrop's talented Whorf family of painters, actors, producers, and commercial artists.

A small area within Winthrop, encompassing these five residential properties included in the Inventory of Historic and Archaeological Assets of the Commonwealth, would be affected by the net increase in the 65 dB DNL contour associated with the Preferred Alternative.

Summary of Impacts and Mitigation for Historic Properties

FAR Part 150 provides that all land uses are considered to be compatible with noise levels less than 65 dB DNL and that commercial and manufacturing land uses are compatible land uses within the 65 dB to 70 dB DNL (FAR Part 150, Appendix A, Table 1). Commercial and industrial portions of historic properties affected by the Preferred Alternative remain below the 70 DNL noise compatibility guideline. Therefore, the existing commercial and industrial uses within those historic areas are compatible land uses.

FAR Part 150 further provides that residential land uses are not compatible within the 65 dB DNL, and if already in areas of 65 dB DNL or higher, that increases of 1.5 dB DNL or less are not significant. Moreover, FAA does allow for noise impacts to be mitigated through sound insulation of affected residential structures.

The FAA and Massport propose to mitigate noise impacts by sound insulating all affected residences, historic and non-historic, that fall within the largest 65 dB DNL contour for the Preferred Alternative. The structures to be included within the noise mitigation program would be subject to a detailed block-by-block analysis during project implementation. All sound insulation of historic structures would be undertaken in compliance with applicable federal and state guidelines to ensure protection of the resources. Preservation measures to maintain the existing form, integrity, and materials of the historic properties would be accomplished in accordance with the Secretary of the Interior's Standards for the Treatment of Historic Properties (36 CFR 68) (Secretary's Standards). The FAA and Massport would consult with the MHC as it has done previously with sound insulation of historic structures impacted by other Logan Airport projects (i.e., South Boston).

The FAA has determined that the sound insulation mitigation proposed under the Preferred Alternative has the potential to cause effects on historic properties (36 CFR 800.3), but such effect would not be adverse on historic properties if sound insulation is undertaken in accordance with the Secretary's Standards. As such, the FAA has determined that a sound insulation program implemented under the Preferred Alternative would have no adverse effect (36 CFR 800.5 (b)) on significant historic properties. The MHC has concurred with the no adverse effect finding (see Appendix H for a copy of the MHC letter to FAA, December 21, 1999).

In addition, since the noise effects of the Preferred Alternative will be mitigated, the normal activity of the Section 4(f) resources will not be affected by the proposed action. The proposed improvements at Logan Airport will neither incorporate land from the Section 4(f) resource nor affect the normal activity or aesthetic value of a public park, recreation area, wildlife refuge or historic site. Therefore, as the Preferred Alternative does not substantially impair a historic site or district, the FAA has determined that Section 4(f) is not applicable.

FAA has also determined that there are no feasible or prudent Alternatives to the Preferred Alternative that would achieve the delay reduction, safety, transportation, noise distribution and other objectives of the Preferred Alternative. Therefore, even if the noise levels associated with the Preferred Alternative were determined to interfere with the normal activity associated with the two identified historic districts (which they do not), the FAA concludes that the sound insulation proposed for those structures includes all possible planning to minimize harm resulting from that increase in noise.

6.3.3 Other Section 4(f) Resources

In response to the May 7, 1999 EOEA Certificate, an assessment of impacts to parklands was conducted for the Preferred Alternative. There are no parklands, historic properties or sites, or other Section 4(f) resources on the airfield in the area of the proposed runway and taxiway improvements. Therefore, there are no direct impacts to Section 4(f) resources from the implementation of the Preferred Alternative. In addition, the Preferred Alternative will not use any portion of a park, recreation area, or other Section 4(f) resources.

The analysis of potential noise indirect impacts associated with the Preferred Alternative was performed by comparing the 65 dB DNL contour for the No Action Alternative and the Preferred Alternative for the 29M Low Fleet scenario. No parklands were identified in those areas where the 65 dB DNL contour for the Preferred Alternative extended beyond the 65 dB DNL contour for the No Action Alternative. As depicted in Figure 6.3-4, the Arnold Arboretum, Emerald Necklace, and Franklin Park are well outside the 65 dB DNL noise contours associated with the Preferred Alternative. Therefore, the Preferred Alternative will have no impact on these parklands.

The noise contour map also depicts that the Boston Harbor Islands, while within the existing No Action Alternative's 65 dB DNL noise contours, will have no noise increase with the Preferred Alternative. In addition, the Boston Harbor Islands National Recreation Area is located under existing FAA approved flight tracks, many designed by FAA and Massport to minimize noise over residential areas associated with Logan Airport operations. For example, the use of Runway 15R for late night (midnight to 6:00 AM) takeoffs and Runway 33L for late night landings keeps aircraft flight tracks over Boston Harbor, making them the most desirable runways for noise abatement. According to the legislation that established the Boston Harbor Islands Recreational Area:

"the present and future maintenance, operation, improvement, and use of Boston-Logan International Airport and associated flight patterns from time to time in effect shall not be deemed to constitute the use of publicly owned land or a public park, recreation area, or other resource within meaning of section 303(c) of title 49, United States Code, and shall not be deemed to have a significant effect on natural, scenic, and recreation assets with the meaning of section 47101(h)(2) of title 49, United States Code."[5]

Therefore, Boston Harbor's National Recreation Area is considered to be a compatible land use.

The dispersion analysis conducted for the purposes of the air quality assessment (see Section 6.4 of this Chapter) indicates no violation of the National Ambient Air Quality Standards (NAAQS) at any of the 12 modeled receptors. Each of the receptors, or locations for which air pollutant concentrations are modeled, is closer to Logan Airport than Arnold Arboretum, Harbor Islands, or the series of parks in the Emerald Necklace.

The receptors at Union Park, C and Broadway, and Castle Island lie closest to these parks, and concentrations at these locations are lowest under the Preferred Alternative and highest under the No Action Alternative but always lower than the NAAQS. Because the receptors nearest the airport do not have modeled concentrations above the NAAQS, it can be concluded that the more distant park locations will also have concentrations that meet the standards and will not experience adverse air quality impacts.

6.3.4 Social Impacts

This section discusses the social impacts of the Preferred Alternative on the surrounding communities in accordance with FAA environmental review criteria. The Environmental Justice Analysis is presented in Section 6.8. Implementation of any of the Airside Project alternatives would occur on the airport, and therefore there will be no division or disruption of established communities or orderly planned development as a result. The Alternatives do not require the relocation of any residence or alteration of surface transportation patterns. Construction of unidirectional Runway 14/32 under the Preferred Alternative requires the demolition of two buildings (60 and 61) in the South Cargo area of the airport. Relocation assistance will be provided to affected businesses as required under applicable law, and no appreciable change in employment is expected to result. The following section provides a more detailed discussion of impacts to the South Cargo Area.

6.3.4.1 South Cargo Area

FAA regulations define areas adjacent to runways that must be maintained free of obstructions. These areas are collectively known as protection zones. There are two distinct sources that dictate the development of design guidelines for unidirectional Runway 14/32. The first is the FAA Advisory Circular 150/5300-13, entitled Airport Design, and the second is Federal Aviation Regulation (FAR) Part 77 entitled Objects Affecting Navigable Airspace. The Runway 14/32 centerline profile is required by federal regulation to be the highest point within various defined safety and object free areas and FAR Part 77 surfaces. (See Section 3.2.2.1 for a more detailed discussion of FAA design surfaces.)

The design criteria for the Runway Object Free Area (ROFA), by nature of its large width, becomes the controlling factor for impacts to Logan Airport 's South Cargo and General Aviation Areas. The ROFA for Runway 14/32 (based on a C-III design aircraft category) is 800 feet wide, centered on the runway centerline and extending 1,000 feet beyond each of the runway ends. Within 400 feet on either side of the runway, the areas must be free of objects that protrude above the adjacent runway safety area edge elevation. Aircraft parking is also prohibited within these areas. A portion of Harborside Drive will need to be relocated outside the ROFA at the Runway 14 end for all layout options. There are no other areas in conflict with the ROFA elsewhere along the alignment of the proposed unidirectional Runway 14/32, since the remaining section of the runway would be built on the existing airfield.

The impact of providing a clear ROFA for Runway 14/32 includes the demolition of Buildings 60 and 61 in the South Cargo Area and the elimination of six cargo aircraft parking positions (SC1 through SC6) and approximately nine aircraft parking positions within the General Aviation (GA) Area. The aircraft parking spaces can be dispersed to existing areas on the airfield approved for aircraft parking. These could include designated parking areas at such locations as the North Cargo Area.

The South Cargo Area includes cargo uses and office related-functions. Construction of Runway 14/32 would require Massport to acquire Building 60 and relocate the tenants. This building contains approximately 74,000 square feet and is owned by MLR Management, which has a ground lease from Massport for the site. MLR leases space to Air France, Air General and Nippon Express.

Building 61 is owned by Massport and directly leased to the U.S. Postal Service on a short-term basis as a temporary facility. The U.S. Postal Service has indicated an interest in relocating from its existing space independent of the construction of Runway 14/32. Therefore, demolition of this building would not require a relocation of the tenants.

Relocation assistance for eligible tenants will be provided in accordance with applicable provisions of the "Uniform Relocation Assistance and Real Property Acquisition Policies Act" of the 1970, as amended and Part 24 of 49 CFR, as well as MGL Chapter 79A and implementing regulations. Relocation assistance measures include relocation advisory services and payments for moving and relocation costs. Relocation resources would be available to all business relocatees without discrimination.

The majority of the tenants of Building 60 are involved in the business of consolidating and forwarding freight. This use is not dependent on cargo positions SC1-SC6 located on the adjacent apron. A review of warehouse/distribution facilities in the area indicates that there is some opportunity in the City of Chelsea Airport Overlay District for relocation of these tenants.[6] In addition, new cargo facilities such as the International Cargo Port in South Boston offer opportunities for relocation. The relocation of the tenants of Building 60 is not considered to be a significant social impact.

6 Personal communication, Jay Ash, then Executive Director of the Office of Planning and Development, City of Chelsea, January 16, 1999.

6.4 Air Quality/Odors

This section presents the results of the air quality assessment of the No Action Alternative and Preferred Alternative on future-year air quality conditions. Section 5.4 (Affected Environment - Air Quality / Odors) describes existing air quality conditions in the vicinity of Logan Airport and contains the 1993 Historic Modeled Condition and 1998 Actual Condition results.

6.4.1 Assessment Approach and Methodology

This analysis is based primarily on two air quality impact assessment methods: (1) emissions inventories; and (2) dispersion modeling. Essentially, the emissions inventory results are used to quantify the types and amounts of air emissions associated with Logan Airport, in the vicinity of the airport. The dispersion modeling results enable the evaluation of air quality impacts for individual neighborhoods. This approach is consistent with both FAA guidelines and MEPA requirements.

To the fullest extent possible, the methodology (including models, data sources, assumptions, etc.) used to conduct this assessment is consistent with the methods developed previously for the GEIR / ESPR and Annual Updates / EDRs. Any changes or departures in this analysis from the GEIR / ESPR protocol are discussed in this section, and are largely attributable to the availability of updated information or to other differences attributable to the Airside Project.

The essential elements and results of the emissions inventories and dispersion modeling are discussed separately below. For comparative purposes, results from both the Airside Project and the *1997 Annual Update* air quality analyses are presented. Additional information, data, and other supporting materials used and / or developed in connection with the assessment are contained in Appendix M of the Airside Project Draft EIS / EIR for the 29M Low, 29M High, 37.5M Low, 37.5M High and 45M High future Fleet scenarios. Additional information, data, and supporting materials for the 37.5M High RJ Fleet scenario are contained in Appendix F of this Supplemental DEIS / FEIR.

Consistent with the scope of the Airside Project Draft EIS / EIR, the Airside Project air quality analysis was conducted for the 29M Low Fleet and 37.5M High Fleet scenarios. The 1993 Historic Modeled Condition and the 1998 Actual Condition results are contained in Section 5.4 of this Supplemental DEIS / FEIR.

Because the FAA's Emissions Dispersion Modeling System (EDMS) has become the required model for air quality assessments of aircraft sources since the Airside Project air quality analysis was conducted, a comparison of the EDMS to the Logan Dispersion Modeling System (LDMS) is also presented in this section. For this demonstration, the emissions inventories and dispersion analyses for both models are compared using the Preferred Alternative under the 29M Low Fleet scenario.

6.4.1.1 Emissions Inventories

The emissions inventories represent compilations of air emissions generated by individual Logan Airport sources for each Airside Project Alternative, enplanement level and operational forecast. The emissions inventories also include aircraft ground service equipment, as well as on- and off-site motor vehicle traffic. The results are expressed in units of kilograms / day (kg / day) for each pollutant and emission source. In this way, comparisons between scenarios with the GEIR / ESPR and with SIP goals can be easily made.

The types of air pollutant emissions included in the inventory are CO, NOx, PM_{10}, and volatile organic compounds (VOCs). CO, NOx, and PM_{10} are EPA criteria air pollutants. Because O_3 emissions cannot be calculated directly, total VOCs are used as a surrogate, or "indicator," of O_3-forming pollutants. Similarly, VOCs from low power aircraft operational modes (i.e., taxi-in, taxi-out, and idle / delay) are used as indicators of odor.

For this assessment, as with other airports, the air pollutants SO_2 and lead were not included in the emissions inventories because airports (including Logan) are not identified as significant sources of these emissions.

NOx emissions occur principally in the form of NO when emitted from the fuel combustion process and then are partially oxidized to NO_2 over time and distance. Therefore, in accordance with DEP guidelines, a 25 percent NO-to-NO_2 conversion factor was used in this analysis.

In general, aircraft emissions are primarily a function of aircraft type, engine type, number of operations, and operational times-in-mode. Essentially, aircraft operations have the following six components: approach, landing, taxi-in, taxi-out, take-off, and climb-out. Following conventional air quality analysis methods, airborne emissions are modeled up to 3,000 feet. Aircraft emissions above this altitude do not have any discernable ground level effects near the airport. Ground-based delay periods are also included in the aircraft emissions analysis.

For the Airside Project analysis, the aircraft fleet mix, number of operations, runway use, terminal assignments, and airborne times-in-mode were developed by individual aircraft type. Similarly, ground-based times-in-mode (including taxi-in, taxi-out, taxiway queues, and end-of-runway delay periods) were developed using the Airport Machine model. Aircraft engine types and emission rates were obtained from the FAA. By comparison, the ground-based aircraft times-in-mode for the *1997 Annual Update* air quality analysis were obtained from the *Logan Airport 1993 Annual Update.*

For aircraft ground service equipment and vehicles, Logan-specific data concerning equipment type, service times, loading factors, emission rates and fuel type were obtained from Massport.[5]

Both on- and off-site motor vehicle traffic data were obtained from the *1994/1995 GEIR*. This includes traffic volumes, travel speeds, idle periods, and fleet mix for the on-airport, East Boston, and Regional Study Areas. For the GEIR, East Boston and regional traffic are segregated; however, the Annual Updates only report on airport study area traffic. The EPA MOBILE5b motor vehicle emission rates were used based on DEP recommended input factors.

Emission rates for the Logan Airport central heating/cooling plant were derived from Massport permitting documents[6] for this facility. Similarly, emission rates for the existing and new fuel storage and distribution systems were obtained from Massport documents.[7]

The various sources of data and information used to develop the emissions inventories are listed in Table 6.4-1.

For the Airside Project, both the emissions inventories and dispersion modeling were conducted using the Logan Dispersion Modeling System (LDMS). For the *1997 Annual Update*, only the emissions inventory of the LDMS is used (i.e., dispersion modeling was not conducted in the GEIR). This computer model was developed by Massport and has been reviewed and approved for use at Logan Airport by DEP and EPA Region I. This model is described below.

6.4.1.2 Dispersion Modeling

The LDMS has two components: (1) a module that calculates total emissions for all aircraft operations, GSE, motor vehicles, fuel storage and transfer facilities, and other miscellaneous sources; and (2) the U.S. EPA Industrial Source Complex (ISC) dispersion model that predicts ambient pollutant concentrations.

5 "Logan Airport Emission Factors." February 1992, prepared by KM Chng Environmental, Inc. for Massport.

				EPA	MOBILE5b Emission Factors PART5 Emission Factors		

1 These data used for the *1997 Annual Update* were obtained from the *1992 Final GEIR* (July 1993).

The LDMS is composed of approximately 150 area, volume, and point sources representing the following air emission source groups at Logan:

- Aircraft Operations on:
  - Gate Aprons
  - Taxiways
  - Heads of Runways
  - Runways
  - Airborne to 3,000 feet

- Ground Service Vehicles and Equipment

- Ground Transportation on:
  - Logan Airport Loop Roads (including terminal curb-side idling and parking garage movements)
  - Route 1A (from the tunnels to Neptune Road)
  - Ted Williams Tunnel (TWT) Toll Booths (vehicle idling)
  - I-90 (from the TWT to Route 1A)
  - TWT Vent Building

- Logan Airport Central Heating/Cooling Plant
- Fuel Storage/Transfer Facilities

The locations of these individual sources (including proposed Runway 14/32, the Centerfield Taxiway and other improvements comprising the Preferred Alternative), as well as the 12 community receptors (described below), were obtained from scaled drawings of Logan Airport and its environs.

For the dispersion modeling, the emission rates from each source were varied by hour of the day, based on existing and forecasted activity levels at Logan Airport over a 24-hour period. In addition, one full year of hourly meteorological data, recorded at Logan Airport in 1993, was used to model the simultaneous occurrence of site-specific wind conditions and emission rates.

Ambient levels of CO, NO_2, and PM_{10} were predicted over time periods consistent with the NAAQS and other appropriate guidelines. As discussed above, because there are no standards for ambient VOC levels, surrogate benchmarks were used. As an O_3 indicator, total VOC emissions from all Logan Airport sources were modeled over 24 hours. For odor, low power aircraft emissions of VOCs were modeled over one-hour intervals. In this way, comparisons between scenarios, Alternatives, and regulatory criteria can be easily made. These time periods and criteria are summarized in Table 6.4-2 for all four pollutants.

Table 6.4-2
Dispersion Modeling Averaging Times and Background Levels

Pollutant	Averaging Time	Standards (μg/m3)	Background Concentration (μg/m3)
CO	1-Hour	40,000	4,446
	8-Hour	10,000	2,502-2,262
HC (or VOCs)	1-Hour (odor indicators)	N/A	N/A
	24-Hour (ozone indicators)	N/A	N/A
NO_2	1-Hour	320	163-173
	Annual	100	53-58
PM_{10}	24-Hour	150	45-48
	Annual	50	23

N/A not applicable

In order to account for (1) natural sources (e.g., forest fires, pollen, marine salts, fugitive dust, etc.), and (2) non-airport sources of air emissions located both within and outside the study area, background concentrations of air pollutants were added to the dispersion model results.

Consistent with DEP guidelines, these background levels were derived from monitoring data collected at the Bremen Street station in East Boston. Located adjacent to the northwest boundary of the airport, ambient levels of CO, NO_2, and PM_{10} are recorded at this site (see Table 5.4-3 in Section 5.4.1.2). Because of this proximity, these measured levels likely include emissions from Logan. Therefore, as a highly conservative approach, the upper bounds of these pollutant concentrations were used as the background levels in the dispersion modeling analysis. This results in the "double counting" of Logan-related emissions. Table 6.4-2 also contains these background levels.

To evaluate the air quality impacts of the No Action Alternative and the Preferred Alternative on individual neighborhoods surrounding the airport, 12 receptors were modeled. These receptors represent neighborhood-specific concentrations of air pollutants resulting from the combined effects of airport operations, background levels, and local meteorology. These receptors, illustrated in Figure 6.4-1 and individually described in Table 6.4-3, were specifically selected for this analysis by DEP. As stated previously, the GEIR and its Annual Updates do not include dispersion modeling.

Table 6.4-3
Receptor Location for Dispersion Modeling

Receptor No.	Community	Location
1	East Boston	Jeffries Point Park tennis court, east end of Sumner Street

6.4.2 Airside Project Emissions Inventories and Dispersion Modeling Results

The air quality impacts of the No Action Alternative and the Preferred Alternative are presented and discussed below. According to federal guidance for air quality impact assessments, it is more important to compare future-year emissions with and without the Preferred Alternative than it is to compare current and future-year emissions. Therefore, the presentation of the results of the air quality analysis is focused on comparing the Preferred Alternative to the No Action Alternative.

The air quality analysis results for the No Action Alternative and Preferred Alternative under the 29M Low Fleet and 37.5M High Fleet scenarios are described in Section 6.4.2.1 and 6.4.2.2. The results for all other Alternatives and for previously analyzed future fleets were presented in detail in the Airside Project Draft EIS/EIR. Summary results for these alternatives and future fleet scenarios are also contained in Appendix F of this Supplemental DEIS/FEIR. Section 6.4.4 presents the emissions inventory and dispersion results for the 37.5M High RJ Fleet. The results for the 1993 Historic Modeled Condition and 1998 Actual Condition were presented in Section 5.4.3.2.

To facilitate further comparison, these results are compiled from tables contained in Appendix M of the Airside Project Draft EIS/EIR and represent the total contributions for all Logan Airport sources previously identified as aircraft, GSE, motor vehicles, and other miscellaneous sources. Each set of results is presented by pollutant type.

For comparative purposes, the emissions inventory results from the Logan Airport 1997 *Annual Update*[8] are also provided. These results are based on 29 million (29M) and 37.5 million (37M) annual passengers, respectively.

The air quality assessments employed in both the Airside Project EIS/EIR and GEIR/ESPR Annual Updates consider aircraft emissions in the LTO cycle from a flight altitude of 3,000 feet to landing, taxiing, idling and take-off to 3,000 feet.

The Preferred Alternative airborne delay reductions will also result in reductions of emissions of aircraft in holding patterns, which impact the region, but do not appear in the air quality assessment. The pollutants reduced (largely NOx) will contribute to ozone reduction in the region. In addition, delay reduction results in considerable fuel savings.

6.4.2.1 Emissions Inventory Results

CO Emissions

Based on the results of the emissions inventory, the three primary sources of CO at Logan Airport are ground support equipment, aircraft, and motor vehicles representing

▼

8 The *Logan Airport 1997 Annual Update* was the last Annual Update that included future forecasts (1999/2010).

approximately 50, 35, and 10 percent of the total, respectively, for all future year scenarios and the PreferredAlternative.

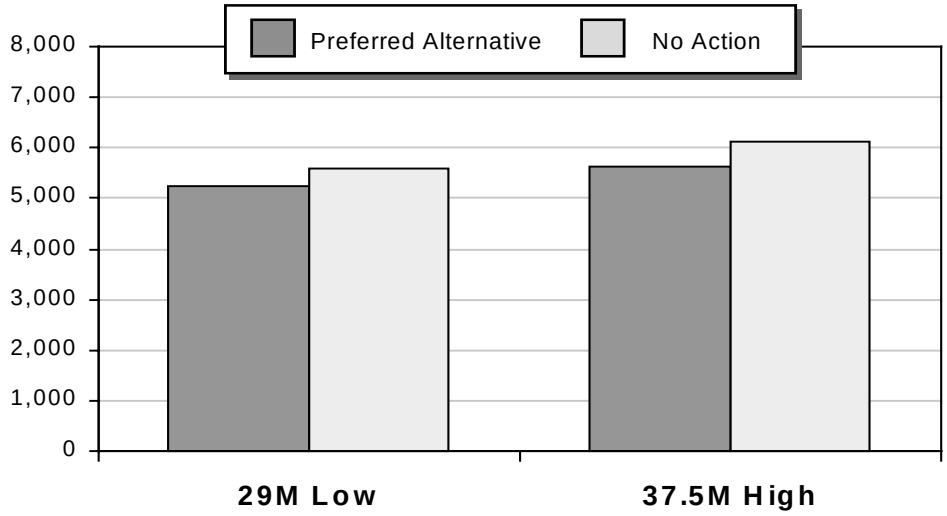
In general, CO emissions from ground support equipment will decrease in the future, as the older equipment is replaced and cleaner-burning fuels are phased in. CO emissions from aircraft will also decline in future years as Stage 2 aircraft are replaced with cleaner-burning Stage 3 aircraft. However, these decreases will be partially offset by the forecasted increase in aircraft operations at Logan Airport over time. Motor vehicle emissions will continue to decline as a result of the federal motor vehicle emissions control program.

As shown in Table 6.4-4 and Figure 6.4-2, the Preferred Alternative is expected to generate a lower amount of total CO emissions than the No Action Alternative. This pattern, the same for all forecasted enplanement and operational levels, is largely attributable to improved airside operating efficiencies associated with the Preferred Alternative.

Table 6.4-4
CO Emissions Inventory - All Sources

Alternative	29M Low Fleet Scenario		37.5M High Fleet Scenario	
	kg/day	tons/year	kg/day	tons/year
Preferred Alternative - All Actions	13,022	5,239	13,976	5,623
No Action Alternative	13,905	5,594	15,236	6,129
1997 Annual Update	14,470	5,821	16,686	6,713

Figure 6.4-2
CO Emissions Inventory – All Sources (ton/year)



When compared to the CO emissions inventory results for future year conditions, contained in the *1997 Annual Update*, the Airside analysis results produce lower values. These differences are due to the refined assessment of airfield operating conditions developed in support of this Supplemental DEIS/FEIR.

NOx Emissions

Aircraft represent the primary source of NOx emissions at Logan Airport generating approximately 75 percent of the total. Ground service equipment, the central heating/cooling plant, and motor vehicles represent roughly 10, 5, and 3 percent of the total, respectively.

NOx emissions from aircraft are expected to increase slightly in future years. This is an unavoidable consequence of phasing in quieter, more fuel-efficient engines. Manufacturers are working to develop engines that will emit less NOx, but this new technology has not been factored into this analysis. NOx emissions from GSE and motor vehicles are also predicted to increase slightly, corresponding to the forecasted increase in operations at Logan, regardless of airside improvements. NOx emissions associated with the central heating/cooling plant are predicted to increase similarly.[9]

As shown in Table 6.4-5 and Figure 6.4-3, the Preferred Alternative is predicted to generate a lower amount of total NOx emissions than the No Action Alternative. Over time, if the airside improvements are not made, emissions are expected to increase at Logan Airport because of the increase in operations and the phasing in of Stage 3 aircraft, which produce more NOx than louder, less fuel efficient Stage 2 aircraft. However, by reducing aircraft delay, implementation of the Preferred Alternative would reduce the rate of NOx increase associated with Stage 3 aircraft.

When compared to the 29M Low Fleet scenario and the 37.5M High Fleet scenario NOx emissions inventory results contained in the *1997 Annual Update*, the Airside analysis results are lower. These differences are due to the refined assessment of airfield operating conditions developed in support of this Supplemental DEIS/FEIR.

Table 6.4-5
NOx Emissions Inventory - All Sources

Alternative	29M Low Fleet Scenario		37.5M High Fleet Scenario	
	kg/day	tons/year	kg/day	tons/year
Preferred Alternative – All Actions	5,362	2,157	6,997	2,815
No Action Alternative	5,491	2,209	7,183	2,890
1997 Annual Update	6,670	2,683	8,343	3,356

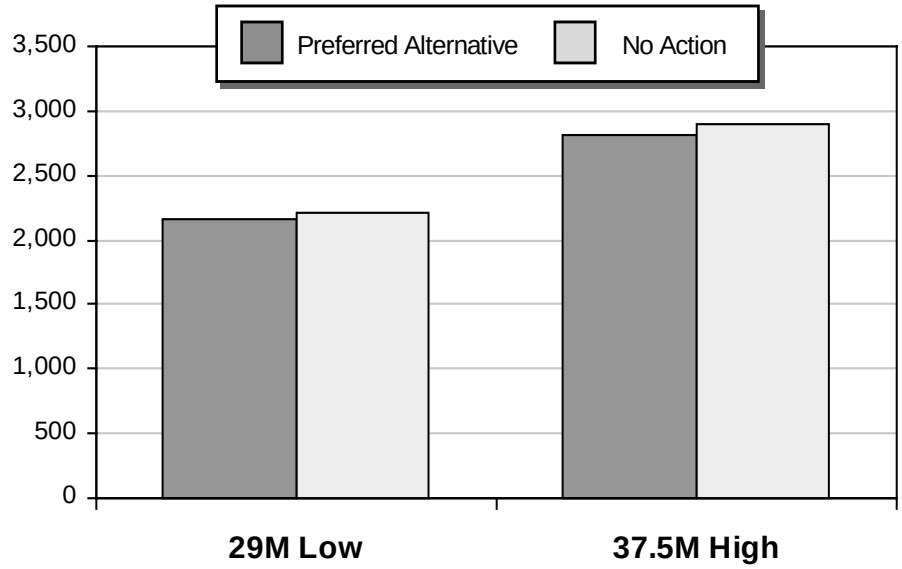
Figure 6.4-3
NOx Emissions Inventory – All Sources (ton/year)



Total VOC Emissions

As a precursor to O_3 formation, VOCs are considered an O_3 indicator in this analysis. In the future, the three primary sources of total VOCs at Logan Airport will be aircraft, fuel storage / transfer facilities, and ground service equipment, representing approximately 40, 30, and 20 percent of the total, respectively.

As discussed above in connection with CO emissions, the VOC content of aircraft exhaust will decline in future years as newer, more efficient, engines are phased in. Similarly, VOC emissions from GSE are expected to decrease as the older equipment is replaced and cleaner-burning fuels are introduced. Evaporative VOCs associated with fuel storage and transfer facilities are a function of the fuel throughput volumes, and are generally well controlled within their containment vessels.

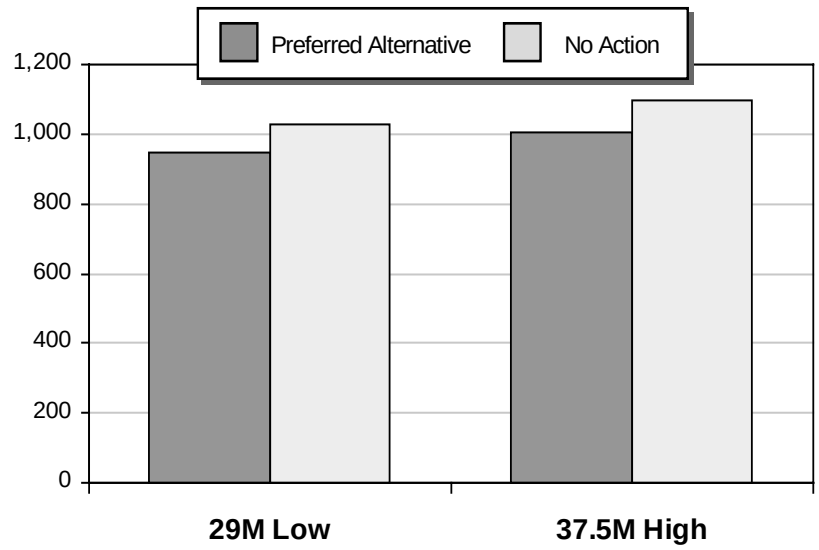
As shown in Table 6.4-6 and Figure 6.4-4, total VOC emissions from all sources at Logan Airport are predicted to increase slightly over time in association with the forecasted increase in operations. However, the Preferred Alternative is expected to generate a lower amount, when compared to the No Action Alternative. This outcome is largely attributable to improved airfield efficiency and shorter delay periods associated with the Preferred Alternative. When compared to the 1999 and 2010 VOC emissions inventory results for the 29M Low and 37.5M High scenarios contained in the *1997 Annual Update*, the Airside analysis values are lower. These differences are due to the refined assessment of airfield operating conditions developed in support of this Supplemental Draft EIS / Final EIS.

Table 6.4-6
Total VOC Emissions Inventory - All Sources (1)

Alternative	29M Low Fleet Scenario		37.5M High Fleet Scenario	
	kg/day	tons/year	kg/day	tons/year
Preferred Alternative - All Actions	2,350	945	2,497	1,005
No Action Alternative	2,553	1,027	2,721	1,095
1997 Annual Update	3,269	1,315	3,207	1,290

(1) Includes aircraft sources, GSE, on-site motor vehicles, and other miscellaneous sources. (See Appendix M of the Airside Project Draft EIS/EIR for individual sources.)

Figure 6.4-4
Total VOC Emissions Inventory – All Sources (tons/year)



Odor-causing Emissions

As discussed previously, VOC emissions associated with aircraft low power operations (i.e., taxi-in, taxi-out, and idle / delay) are considered to be potentially odor causing. Therefore, the same trends in total VOCs described above for aircraft emissions are applicable to these odor-causing VOCs. That is, the VOC content of aircraft exhaust will decline in future years as newer, more efficient aircraft engines are phased in.

As shown in Table 6.4-7 and Figure 6.4-5, the amounts of odor-causing VOC emissions at Logan Airport are not expected to change significantly into the future. However, there is a noticeable reduction in these emissions when comparing the Preferred Alternative to the No Action Alternative. The Preferred Alternative produces lower odor-causing VOC emissions than the No Action Alternative.

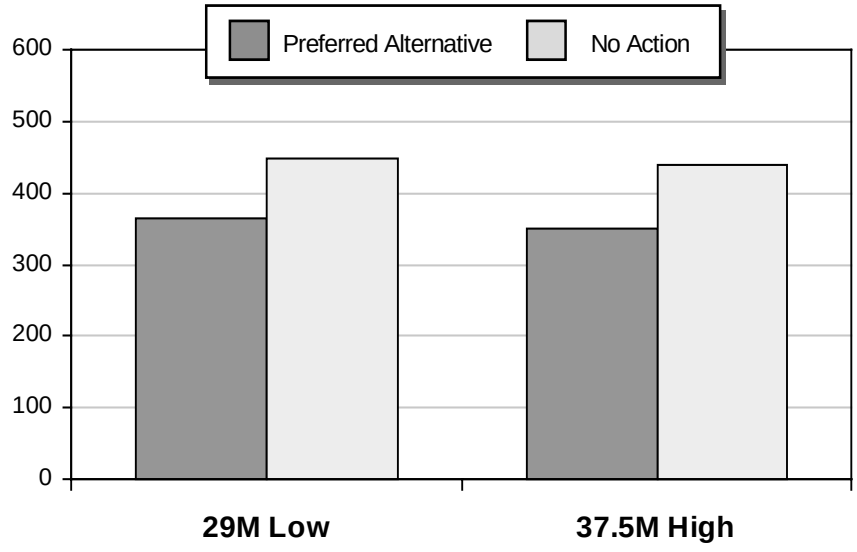
The predicted reduction in odor-causing VOCs is attributable to improved airfield operating conditions and reduced aircraft delay periods associated with the individual Alternatives. Moreover, under the Preferred Alternative, some additional flexibility is gained on how airfield operations are managed, which may lead to further reductions in odor-causing VOC emissions.

Table 6.4-7
Odor-causing VOC Emissions Inventory - All Sources (1, 2)

Alternative	29M Low Fleet Scenario		37.5M High Fleet Scenario	
	kg/day	tons/year	kg/day	tons/year
Preferred Alternative - All Actions	909	366	870	350
No Action Alternative	1,112	447	1,094	440

(1) Includes aircraft sources, ground service equipment, on-site motor vehicles, and other miscellaneous sources. (See Appendix M of the Airside Project Draft EIS/EIR for individual sources.)
(2) Odor-causing VOCs were not included in the *1997 Annual Update*.

Figure 6.4-5
Odor-causing VOC Emissions Inventory – All Sources (ton/year)



PM_{10} Emissions

Aircraft are considered to be the predominant source of particulate emissions, representing roughly 90 percent of the Logan Airport total. Ground service equipment and motor vehicles comprise most of the remaining 10 percent. Notably, particulate matter emission factors for aircraft are not well known. The few studies that exist are generally for military aircraft. Fractionation profiles, which would allow calculation of emissions inventories for PM_{10} and $PM_{2.5}$,do not exist for aircraft emissions of particulate matter. The LDMS uses the few emission factors that do exist and classifies all particulate matter as PM_{10}.

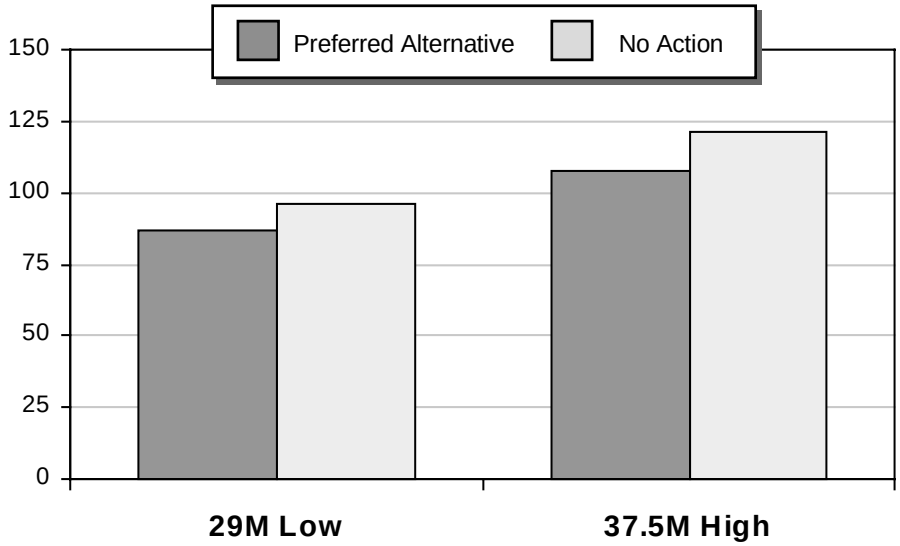
As shown in Table 6.4-8 and Figure 6.4-6, emissions of particulate matter are expected to increase in future years in connection with the forecasted increase in aircraft operations at Logan. However, the amounts associated with the Preferred Alternative are lower than those associated with the No Action Alternative. It is also noteworthy that this analysis does not take into full account the reduction in particulate emissions expected with the newer, more efficient aircraft engines. PM emissions are not included in the *1997 Annual Update* emissions inventories.

Table 6.4-8
PM_{10} Emissions Inventory - All Sources [1,2,3]

Alternative	29M Low Fleet Scenario		37.5M High Fleet Scenario	
	kg/day	tons/year	kg/day	Tons/year
Preferred Alternative - All Actions	217	87	268	108
No Action Alternative	238	96	301	121

1. Includes aircraft sources, ground service equipment, on-site motor vehicles, and other miscellaneous sources. (See Tables EI1-4, EI2-4, EI3-4, and EI4-4 in Appendix M of the Airside Project Draft EIS/EIR for individual sources).
2. PM emissions are not included in the *1997 Annual Update*.
3. Assumes all PM emissions are PM_{10}.

Figure 6.4-6
PM_{10} Emissions Inventory – All Sources (ton/year)



Off-Site Motor Vehicle Emissions

For the purposes of this assessment, off-site motor vehicle emissions are attributable to passenger, employee, and cargo transport vehicles traveling to and from Logan Airport on the local and regional roadway network. As discussed previously, the basis, data, and methods used to develop this analysis were obtained from the *1994/1995 GEIR*.

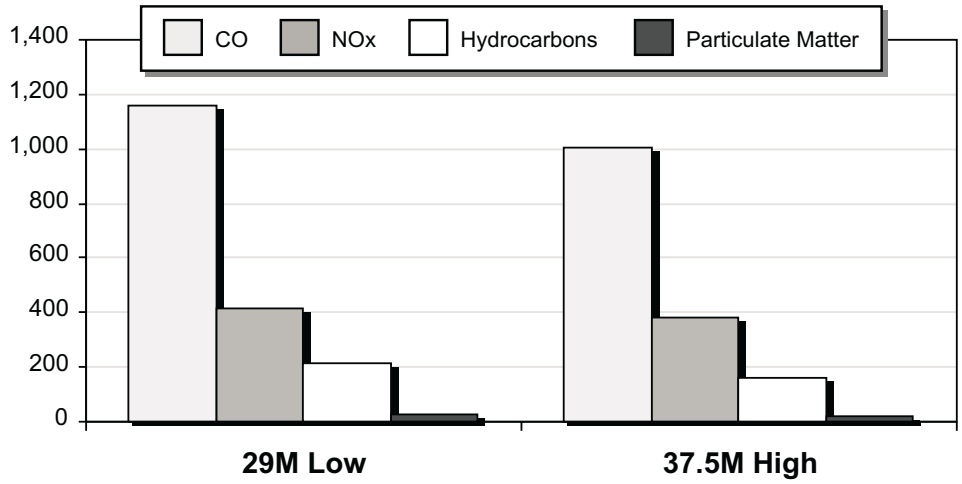
The results of the off-site motor vehicle emissions inventory are summarized in Table 6.4-9 and illustrated in Figure 6.4-7. As shown, emissions of CO, NOx, VOCs, and particulate matter (PM) are expected to decline over the long term. This reduction is largely attributable to the federal motor vehicle emissions control program that mandates the development of more fuel efficient, cleaner-burning motor vehicles nationwide. Part of the reduction is also associated with DEP programs designed to reduce motor vehicle emissions statewide.

Table 6.4-9
Off-Site Motor Vehicle Emissions (1)

Pollutant	Near Term 29M Low Fleet Scenario		Long Term 37.5M High Fleet Scenario	
	kg/day	tons/year	Kg/day	tons/year
CO	2,883	1,160	2,506	1,008
NO_2	1,027	413	948	381
VOCs	526	212	401	161
PM	60	24	41	17

(1) Includes airport-related motor vehicles in the East Boston and Regional Study Areas.

Figure 6.4-7
Off-Site Motor Vehicle Emissions Inventory (tons/year)



6.4.2.2 Dispersion Modeling Results

As previously discussed, ambient (outdoor) levels of air pollutants were predicted at 12 community sites (called receptors) using the LDMS. In this way, the impacts of the No Action Alternative and the Preferred Alternative can be individually assessed in each neighborhood and the results can be compared directly to state and federal air quality standards or guidelines.

The dispersion modeling results for the No Action Alternative and the Preferred Alternative under the 29M Low and 37.5M High Fleet scenarios are discussed below. For ease in assimilating these findings, only the highest levels predicted at all 12 receptors are reported. The assumption is that pollutant levels at the 11 other receptors will be less by comparison. Exceptions to this reporting technique are the reported ozone and odor indicator levels, which are given as spatially averaged values.

The 1993 Modeled Historic Condition dispersion model results were presented in Section 5.4.3.2. Dispersion modeling is not included in the *1997 Annual Update* air quality analyses.

29M Low Fleet Scenario Dispersion Model Results

As shown in Table 6.4-10, the highest predicted levels of CO, NO_2, and PM_{10} are expected to be well within the air quality standards and guidelines for these pollutants. A comparison of the No Action Alternative and the Preferred Alternative indicates that the Preferred Alternative results in lower concentrations of CO (1- and 8-hour), NO_2 (1-hour), and the ozone / odor indicators. For NO_2 (annual) and PM_{10} (24-hour and annual), there is no difference between the No Action Alternative and the Preferred Alternative results. Because of the relative similarity of these results overall, there should be no discernable differences in ambient air quality conditions at any of the receptors under either Alternative.

Table 6.4-10
29M Low Fleet Scenario Dispersion Model Results Summary

Pollutant/Parameter	Community Air Concentration(µg/m³)		Air Quality Standard
	Preferred Alternative	No Action Alternative	(µg/m³)
CO, 1-hour, highest 2nd high	5,676	6,002	40,000
CO, 8-hour, highest 2nd high	2,734	2,808	10,000
NO_2, 1-hour, highest 2nd high	255	263	320
NO_2, annual, highest	55	55	100
PM_{10}, 24-hour, highest 2nd high	48	48	150
PM_{10}, annual, highest	24	24	50
Ozone indicator, Total VOC, 24-hour, spatially-averaged highs	16	18	N/A
Odor indicator, Aircraft idle Mode VOC, 1-hour, spatially-averaged highs	90	96	N/A

N/A Not applicable as it is used as an indicator of potential ozone formation and is not comparable to any standard.

37.5M High Fleet Scenario Dispersion Model Results

As shown in Table 6.4-11, under this scenario the highest predicted levels of CO, NO_2, and PM_{10} are again well within the air quality standards and guidelines. When comparing the results between the No Action Alternative and the Preferred Alternative, there are still no significant differences for any of the pollutants.

Based on the results of the emissions inventories and the dispersion modeling, the following findings on the effects of the Airside Project are evident: (1) there are no predicted violations of any state and federal standards or guidelines under any future scenarios or Alternatives; and (2) the overall impacts associated with the Preferred Alternative are beneficial or the same when compared to the No Action Alternative.

Results of Air Quality Impact Analyses

To comply with the Clean Air Act Amendments of 1990 (CAAA) and the NEPA, FAA has made the following findings for project-related air quality impacts.

Because the proposed action is located in an ozone non-attainment area, the FAA must determine if the proposed action is consistent with the state implementation plan (SIP). General Conformity requirements mandated by Section 176(c) of the CAAA require the FAA to do so. To make this determination, FAA must compare the emissions resulting from the Preferred Alternative against those emissions that would have occurred under the No Action scenario.

Table 6.4-11
37.5M High Fleet Scenario Dispersion Model Results Summary

Pollutant/Parameter	Community Air Concentration (µg/m³)		Air Quality Standard
	Preferred Alternative	No Action Alternative	(µg/m³)
CO, 1-hour, highest 2nd high	5,743	5,798	40,000
CO, 8-hour, highest 2nd high	2,792	2,844	10,000
NO_2, 1-hour, highest 2nd high	282	275	320
NO_2, annual highest	56	56	100
PM_{10}, 24-hour, highest 2nd high	48	49	150
PM_{10}, annual highest	24	24	50
Ozone indicator, Total VOC, 24-hour, spatially-averaged highs	18	20	N/A
Odor indicator, Aircraft idle mode VOC, 1-hour, spatially-averaged highs	115	119	N/A

N/A Not applicable as it is used as an indicator of potential ozone formation and is not comparable to any standard.

Based on the analyses of NOx and VOCs (Tables 6.4-5 and 6.4-6, respectively), FAA has determined that the proposed project's net annual emissions (Preferred Alternative emission levels minus No Action Alternative emissions) will be less than the applicable NOx and VOC emission levels in 40 CFR 93.153(b) for all future conditions analyzed. In addition, FAA analysis of these levels shows that the Preferred Alternative would not be "regionally significant" because it would not cause 10 percent of the total emissions inventories for NOx or VOC in the Boston ozone nonattainment area. Accordingly, FAA has determined that the Project is presumed to conform to the SIP in accordance with Section 176 (c) of the CAAA.

For NEPA purposes, FAA must also assess the air quality impacts of Project Alternatives under consideration. FAA completed dispersion modeling for the Preferred Alternative and for the No Action Alternative. Analysis of Table 6.4-11 clearly shows that the proposed project would not exceed any NAAQS. Accordingly, FAA has determined that the Preferred Alternative would not cause significant air quality impacts.

6.4.3 Comparison of the Logan Dispersion Modeling System and Emissions and Dispersion Modeling System

As stated previously, since the completion of the scope of work for the Airside Project Draft EIS/EIR, the FAA's EDMS has become the required model for aviation sources Airside Project Draft EIS/EIR. In order to provide assurance that the LDMS provides results similar to EDMS, a comparison of the two models was conducted for the Preferred Alternative under the 29M Low Fleet scenario. This analysis indicates that the choice of model would not affect the outcome of the air quality assessment.

Both EDMS and LDMS have two components: an emissions inventory calculation and a dispersion model. The emissions inventory methodology for both models is very similar, with emission factors being multiplied by the number of aircraft operations, engines, and operating duration for each mode. The emission factors in LDMS were obtained from the FAA Engine Emission Database (FAEED), which is also the source of many emission factors in EDMS. Notably, EDMS does not contain emission factors for aircraft-generated PM_{10}, and LDMS does not have emission factors for oxides of sulfur. Because of their parallels, the emission factors in the two models are comparable. The principal difference in the emissions inventory portion of the two models is the treatment of times-in-mode. LDMS allows the user to input Logan-specific times-in-mode for all modes of operation, based on the output of Logan-specific airport operational models. EDMS, however, allows the user to input only taxi/idle time and automatically calculates times-in-mode for approach, takeoff, and climbout based on the mixing height. The emissions inventories calculated by the two models are compared in Table 6.4-12.

Table 6.4-12
Preferred Alternative 29M Low Fleet Scenario
Emissions Inventory Comparison

Pollutant	EDMS		LDMS	
	kg/day	Tons/year	kg/day	tons/year
CO	15,143	6,092	13,022	5,239
VOCs (1)	1,963	790	2,350	945
NOx	7,198	2,896	5,362	2,157
SO_x	538	216	N/A	N/A
PM_{10} (2)	90	36	217	87

N/A - not applicable
(1) Hydrocarbon emissions calculated in EDMS are being used to represent VOCs in this comparison.
(2) PM_{10} emission factors for aircraft are not included in EDMS. Therefore, the PM-10 total for EDMS includes GSE, motor vehicles and stationary sources, but not aircraft.

As shown in the table, EDMS projects higher total emissions of CO and NOx, while estimating lower emissions of VOCs and PM_{10} emissions than LDMS. These differences would be carried across all Alternatives and scenarios if they were modeled using EDMS. Importantly, the relationship of the Alternatives to each other is not expected to be greatly affected by the choice of model. In other words, the Preferred Alternative will be associated with the lowest amount of emissions among the Alternatives, and the No Action Alternative will be associated with the highest emissions, regardless of the model used.

The second element of the two models is dispersion evaluation. LDMS uses the model ISCST3 (Industrial Source Complex Short-Term), a Gaussian plume dispersion algorithm. ISCST3 is an EPA-preferred model for a variety of reasons. It has the ability to treat point, area, line, and volume sources; deposition; downwash; and plume rise. The dispersion component in EDMS uses EPA's PAL2 (Point Area and Line) and CALINE3 (California Line Source), which are also Gaussian plume models. Both LDMS and EDMS have the ability to incorporate actual meteorological data. There are inherent differences among the algorithms in the two models, but the use of Gaussian plumes in both models leads to similarities in results. The results of the EDMS dispersion analysis of the Preferred Alternative under the 29M Low Fleet scenario are shown in Figures 6.4-8 through 6.4-10 and compared to the LDMS results. Complete dispersion modeling results are in Appendix F.

Figure 6.4-8
CO Dispersion Comparison (Second Highest Level)

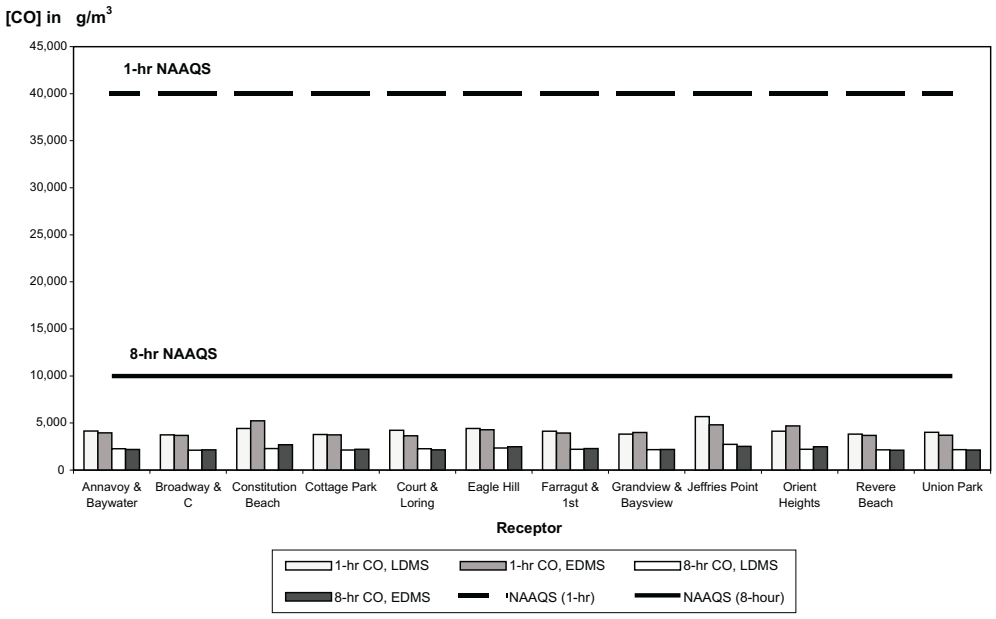


Figure 6.4-9
NO_2 Dispersion Comparison (Highest Annual Mean and Second Highest 1-Hour Level

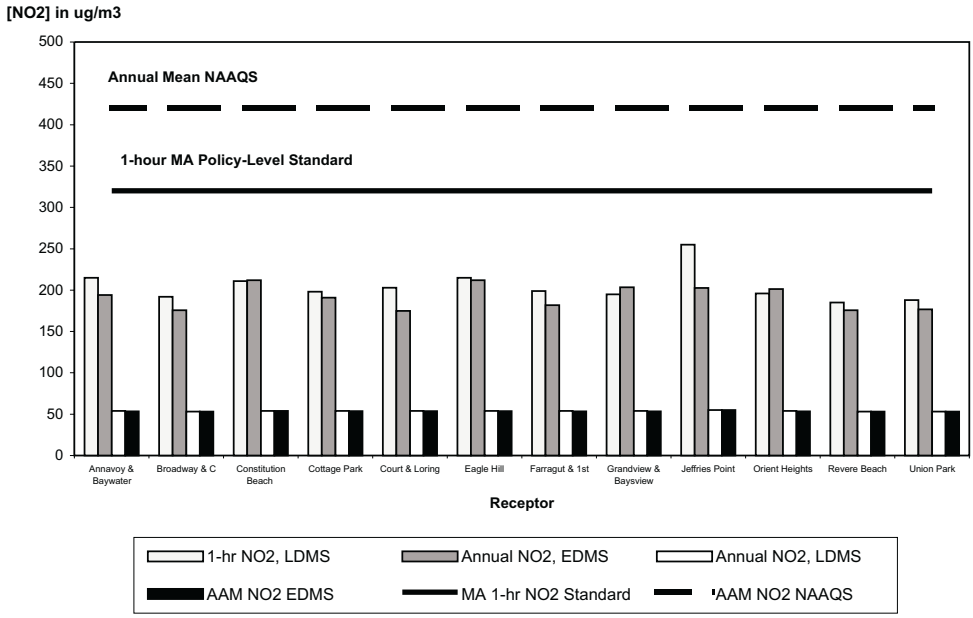

Figure 6.4-10
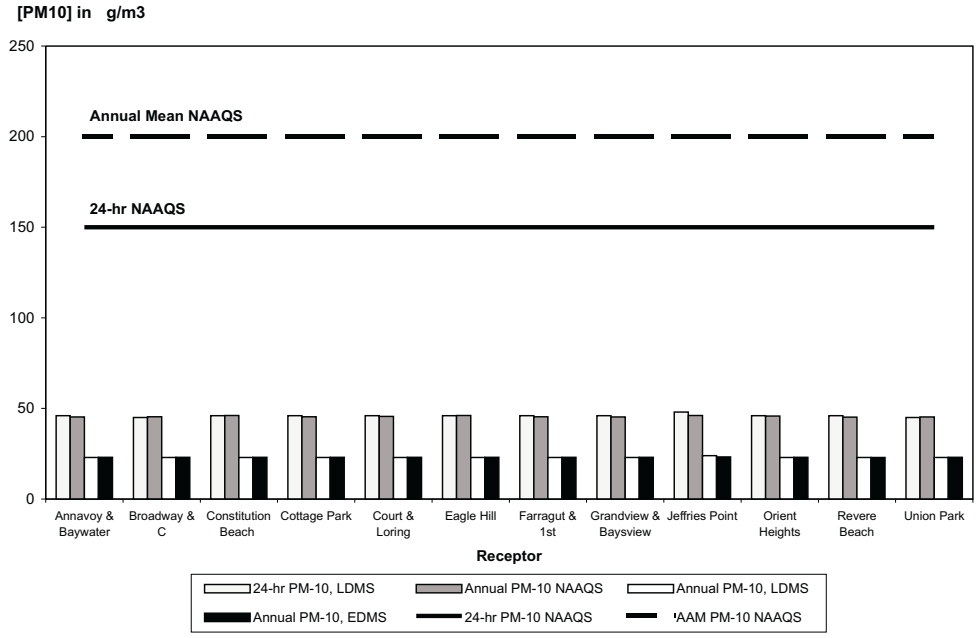
PM_{10} Dispersion Comparison
Highest Annual Mean and Second Highest 24-Hour Level



As shown in the figures, the two models have similar results. The predicted concentrations are, on average, two percent higher with LDMS. The higher results generated by LDMS mean that this model is, in general, conservative. The only exception to the conservative nature of LDMS is with CO concentrations for an eight-hour averaging time, which are two percent higher, on average, with EDMS. Nonetheless, all concentrations are well within the NAAQS for all modeled pollutants with either model. The variation between modeled concentrations at each receptor can likely be attributed to differences in the nuances of the modeling algorithms as well as inevitable variance in the manner of user input (e.g., time-in-mode, as mentioned previously).

Although EDMS and the LDMS have somewhat different components, their methodologies and, more importantly, their results are similar. The comparison of the two conducted for this analysis indicates that if all emissions inventories were prepared with EDMS, all action alternatives including the Preferred Alternative would still result in air quality benefits, when compared to the No Action Alternative. Furthermore, the dispersion modeling shows that results of the two models are comparable, and that there are no modeled violations of the NAAQS.

6.4.4 Air Quality Results for the 37.5M High RJ Fleet

The air quality analysis has been updated since the Airside Project Draft EIS/EIR to reflect an additional long-term planning forecast of aircraft operations and fleet mix at Logan. To estimate the scope of impacts associated with these revisions, the LDMS was applied to the Preferred Alternative and the No Action Alternative. The methodology for this analysis is consistent with that used for the Airside Project Draft EIS/EIR modeling efforts, with changes made only to the aircraft, auxiliary power units, and GSE. The emissions inventory and dispersion modeling results are presented in this section.

6.4.4.1 Emissions Inventory Results

The additional 37.5M High RJ Fleet forecast for Logan Airport produced the need to amend the emissions associated with aircraft, auxiliary power units, and GSE. The other emissions sources, however, have been analyzed previously and are not re-calculated here. Previous estimates for these sources (e.g., motor vehicles and stationary sources) are not expected to change for the 37.5M High RJ Fleet forecast.

CO Emissions

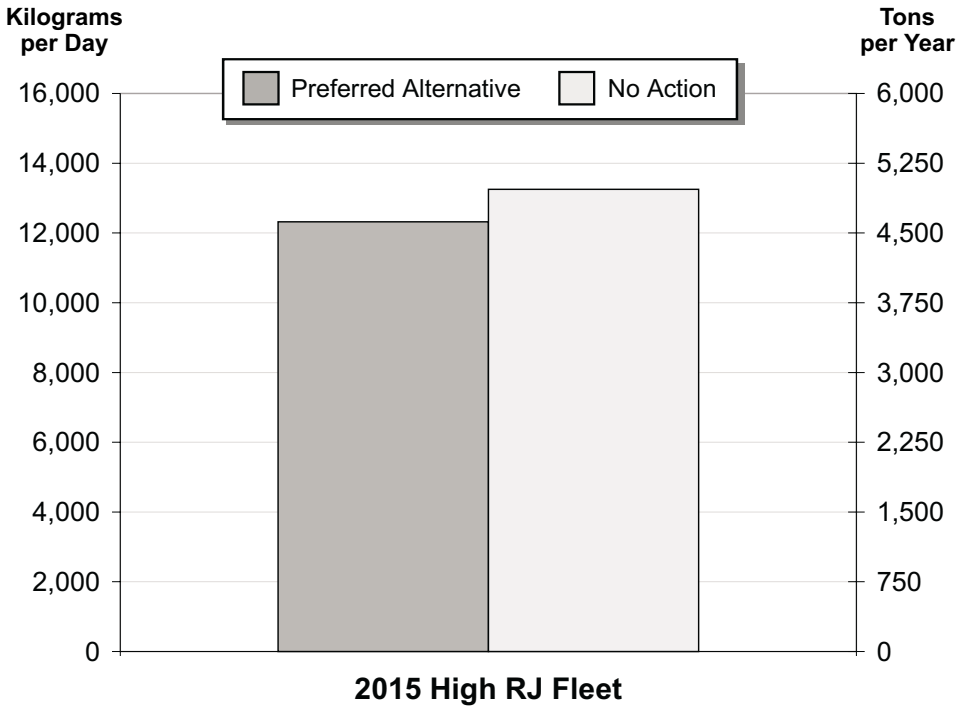
CO emissions will decrease in the future as a result of several factors: cleaner-burning Stage 3 aircraft, tighter motor-vehicle emissions controls, and alternative fuels in GSE. However, these decreases will be partially offset by the forecasted increase in aircraft operations at Logan Airport over time. As shown in Table 6.4-13 and Figure 6.4-11, the Preferred Alternative is expected to generate a lower amount of total CO emissions, when compared to the No Action Alternative, at all forecasted enplanement and operational levels. This emissions reduction is largely attributable to improved airfield operating efficiencies associated with the Preferred Alternative.

Table 6.4-13
CO Emissions Inventory - All Sources (1)

Alternative	37.5M High RJ Fleet Scenario	
	kg/day	tons/year
Preferred Alternative - All Actions	12,322	4,958
No Action Alternative	13,253	5,332

Includes aircraft sources, GSE, on-site motor vehicles, and other miscellaneous sources.
(See Appendix M of the Airside Project Draft EIS/EIR and Appendix F of this Supplemental DEIS/FEIR for individual sources.)

Figure 6.4-11
CO Emissions Inventory – All Sources



NOx Emissions

Aircraft are projected to continue to represent the primary source of NOx emissions at Logan, generating approximately 78 percent of the total under either the Preferred Alternative or the No Action Alternative. GSE, the central heating/cooling plant and motor vehicles represent roughly 11, 8, and 3 percent of the total, respectively. NOx emissions from all sources other than motor vehicles are expected to increase in future years.

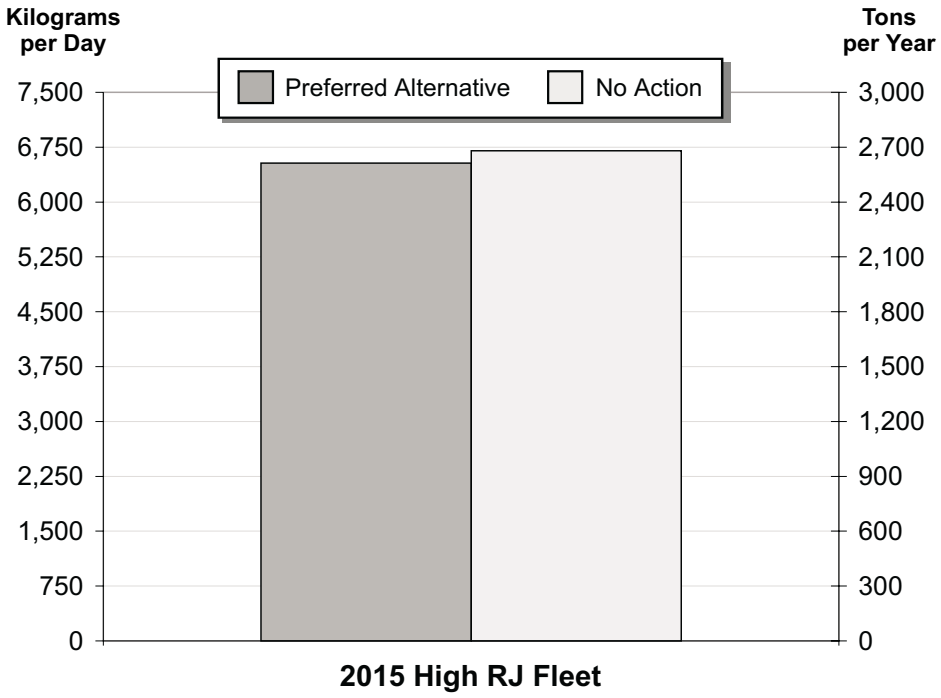
As shown in Table 6.4-14 and Figure 6.4-12, the Preferred Alternative is predicted to emit a smaller amount of NOx than the No Action Alternative. The improvements in the Preferred Alternative would help offset the rate of NOx increase associated with Stage 3 aircraft and the growth in aircraft operations by improving airfield efficiency and shortening delay periods.

Table 6.4-14
NOx Emissions Inventory - All Sources (1)

Alternative	37.5M High RJ Fleet Scenario	
	kg/day	tons/year
Preferred Alternative – All Actions	6,531	2,628
No Action Alternative	6,703	2,697

Includes aircraft sources, GSE, on-site motor vehicles, and other miscellaneous sources.
(See Appendix M of the Airside Project Draft EIS/EIR and Appendix F of this Supplemental DEIR/FEIR for individual sources.)

Figure 6.4-12
NOx Emissions Inventory – All Sources



Total VOC Emissions

As with previous analyses in support of the Draft EIS / Final EIR, VOCs are considered an O3 indicator in this analysis. The three primary sources of total VOCs at Logan Airport are projected to be fuel storage and handling, GSE, and aircraft.

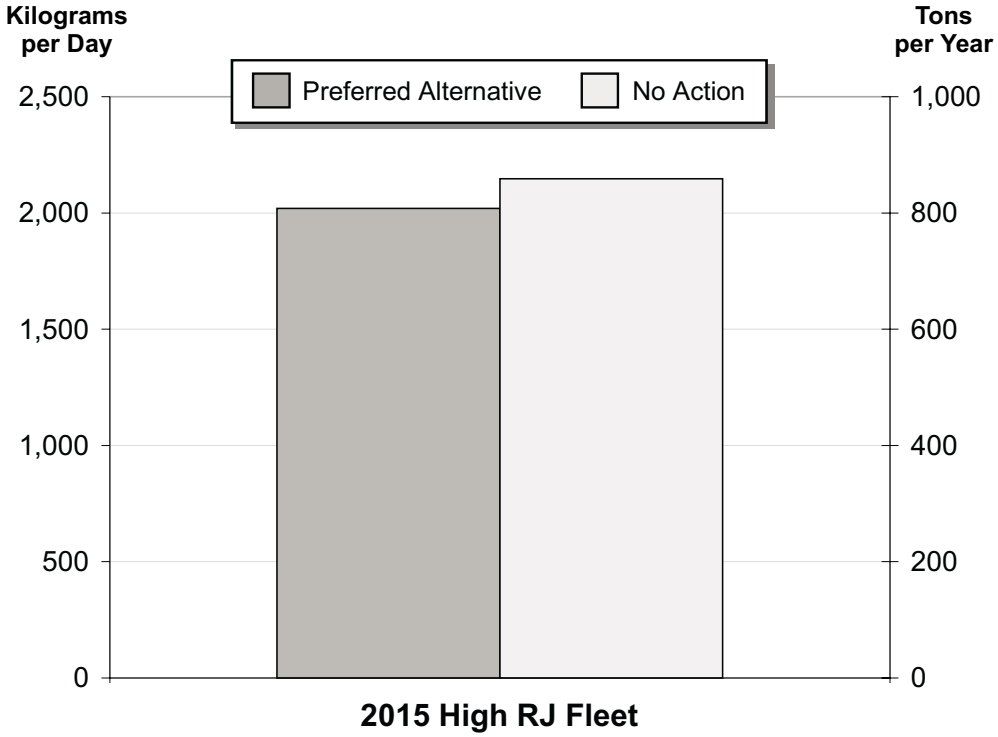
As shown in Table 6.4-15 and Figure 6.4-13, total VOC emissions are predicted to decrease over time, primarily as a result of the lower-VOC profiles associated with the High RJ Fleet. The Preferred Alternative is expected to generate a lower amount of VOCs than the No Action Alternative. This outcome is largely attributable to improved airfield efficiency and shorter delay periods associated with the Preferred Alternative.

Table 6.4-15
Total VOC Emissions Inventory - All Sources (1)

Alternative	37.5M High RJ Fleet Scenario	
	kg/day	tons/year
Preferred Alternative – All Actions	2,019	812
No Action Alternative	2,147	864

Includes aircraft sources, GSE, on-site motor vehicles, and other miscellaneous sources.
(See Appendix M of the Airside Project Draft EIS/EIR and Appendix F of this Supplemental DEIR/FEIR for individual sources.)

Figure 6.4-13
Total VOC Emissions Inventory – All Sources



Odor-causing Emissions

The portion of VOC emissions associated with aircraft low power operations are considered to be indicative of odors, and this emissions category follows the same patterns as those described above for total emissions of VOCs. In other words, odor-related VOCs are expected to decrease over time and be lower with the Preferred Alternative than with the No Action Alternative, as shown in Table 6.4-16 and Figure 6.4-14.

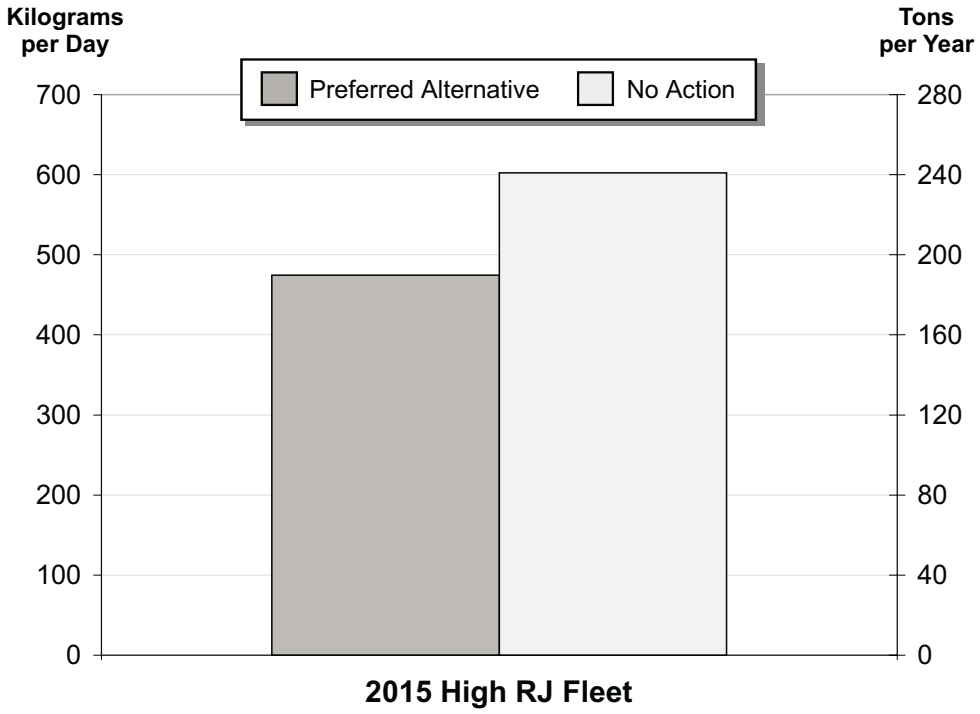
This predicted reduction in odor-causing VOCs is attributable to the aircraft fleet and to improved airfield operating conditions and reduced aircraft delay periods associated with the individual Alternatives.

Table 6.4-16
Odor-causing VOC Emissions Inventory - All Sources[1]

Alternative	37.5M High RJ Fleet Scenario	
	kg/day	tons/year
Preferred Alternative - All Actions	475	191
No Action Alternative	602	242

Includes aircraft sources, GSE, on-site motor vehicles, and other miscellaneous sources.

Figure 6.4-14
Odor-causing Emissions Inventory – All Sources



PM_{10} Emissions

This analysis is based on the LDMS, which uses the few available data for PM_{10} emitted from aircraft. Aircraft are projected to remain the predominant source of particulate emissions, with GSE, miscellaneous sources, and motor vehicles accounting for roughly 5 percent each.

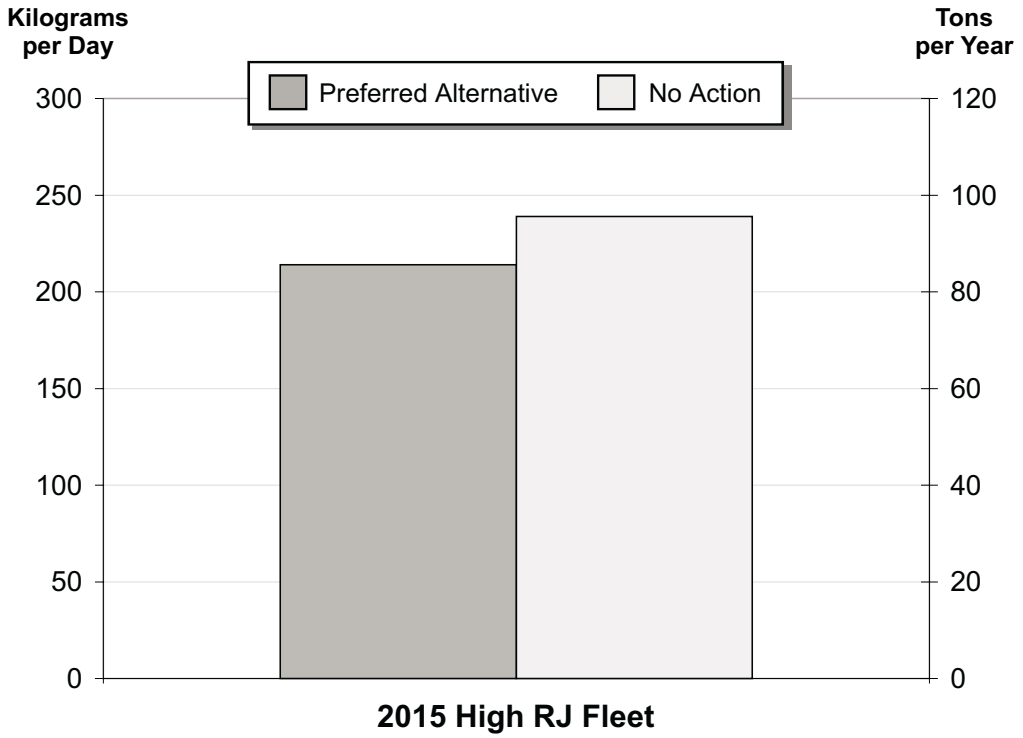
As shown in Table 6.4-17 and Figure 6.4-15, emissions of particulate matter are expected to decrease in future years, a result of decreases from all sources other than miscellaneous sources. In addition, the amounts associated with the Preferred Alternative are lower than those associated with the No Action Alternative.

Table 6.4-17
PM_{10} Emissions Inventory - All Sources [1,2,]

Alternative	37.5M High RJ Fleet Scenario	
	kg/day	tons/year
Preferred Alternative	214	86
No Action Alternative	239	96

(1) Includes aircraft sources, GSE, on-site motor vehicles, and other miscellaneous sources. (See Appendix M of the Airside Project Draft EIS/EIR and Appendix F in this Supplemental DEIS/FEIR for individual sources.)
(2) Assumes all PM emissions are PM_{10}.

Figure 6.4-15
PM_{10} Emissions Inventory – All Sources (ton/year)



6.4.4.2 Dispersion Modeling Results

As with previous analyses, ambient levels of air pollutants were predicted at 12 receptors using the LDMS to asses the impacts of the project alternatives in each neighborhood and to compare the results air quality standards and guidelines. These receptors are shown in Figure 5.4-1.

The dispersion modeling results are discussed below, with the highest levels of CO, NOx, and PM_{10} predicted at any one receptor. The assumption is that pollutant levels at the 11 other receptors will be lower than this highest reported value. The reported ozone and odor indicator levels, which are regional in nature, are given as spatially averaged values.

As shown in Table 6.4-18, the highest predicted levels of CO, NO_2, and PM_{10} are expected to be well within their respective air quality standards and guidelines. Between the Preferred Alternative and the No Action Alternative, the lowest pollutant concentrations generally occur under the Preferred Alternative.[10,11] Because of the relative similarity of these results overall, there should be no discernable differences in ambient air quality conditions at any of the receptors under either Alternative.

▼

10 The maximum concentrations of PM10 are less than 1 µg/m3 lower under the Preferred Alternative than under the No Action Alternative.
11 The 1-hour NO2 level is the only exception to this statement in that the highest level under the Preferred Alternative is slightly higher than the highest level under the No Action Alternative.

Table 6.4-18
37.5M High RJ Fleet Scenario Dispersion Model Results Summary

Pollutant/Parameter	Community Air Concentration (µg/m³)		Air Quality Standard (µg/m³)
	Preferred Alternative	No Action Alternative	
CO, 1-hour, highest 2nd high	6,104	6,125	40,000
CO, 8-hour, highest 2nd high	2,884	2,928	10,000
NO_2, 1-hour, highest 2nd high	290	279	320
NO_2, annual, highest	55	56	100
PM_{10}, 24-hour, highest 2nd high	48	48	150
PM_{10}, annual, highest	24	24	50
Ozone indicator, Total VOC, 24-hour, spatially averaged highs	16	17	N/A
Odor indicator, Aircraft idle Mode VOC, 1-hour, spatially averaged highs	108	111	N/A

N/A Not applicable as it is used as an indicator of potential ozone or odor formation and is not comparable to any standard.

The emissions inventory and dispersion modeling for the 37.5M High RJ Fleet show that there are no predicted violations of any state and federal standards or guidelines under any future scenarios or Alternatives, and that the overall impacts associated with the Preferred Alternative are either beneficial or imperceptible, when compared to the No Action Alternative.

6.5 Biotic Communities

Biotic community impacts include impacts to terrestrial vegetation, wetlands, wildlife, and rare species.

6.5.1 Terrestrial Vegetation

Construction of the runway and taxiway improvement components of the Preferred Alternative will require the conversion of areas of existing upland vegetation to paved surfaces. As described in Section 5.5.1, these vegetated areas generally consist of mowed grasses. In addition, both reconfiguration of the Southwest Corner Taxiway System and construction of Runway 14/32 would convert areas of existing pavement to vegetation. As shown in Table 6.5-1 below, construction of the Preferred Alternative results in the net conversion of 37.6 acres of vegetation to paved area.

Conversion of the vegetated infield areas will reduce the pervious surface area of the airfield and reduce available habitat for resident and transient species. For most of the species occurring on the airfield, the loss of available habitat will not constitute a significant adverse impact. However, portions of the airfield to be converted from grassed upland to paved surface are used by the upland sandpiper (*Bartramia longicauda*) for breeding and nesting. Impacts to this state-listed endangered species are described in Section 6.5.5.

Table 6.5-1
Summary of Airfield Vegetation Impacts

Improvement Concept	Conversion of Vegetation to Paved Area	Conversion of Paved Area to Vegetation	Net Change of Vegetation
Runway 14/32	16.1 acres	13.4 acres	-2.7 acres
Centerfield Taxiway:			
■ North Section	16.8 acres	-	- 30.1 acres
■ South Section	13.3 acres	-	
Extend Taxiway Delta	7.5 acres	-	- 7.5 acres
Taxiway November Realignment	5.3 acres	6.9 acres	+1.6 acres
Southwest Corner Taxiway System Reconfiguration	5.0 acres	6.1 acres	+ 1.1 acres
Total Change of Vegetation			**-37.6 acres**

Source: HNTB, 1999

6.5.2 Wetlands

As described in Section 5.5, the perimeter of the airfield is located within the 100-foot buffer zone of a coastal bank as regulated under the Massachusetts Wetlands Protection Act and associated regulations (310 CMR 10.00 et. seq.). Portions of the buffer zone will be re-graded and vegetated for use as a runway safety area or object free areas for the unidirectional Runway 14/32 (all layout options). The overall linear distance of the buffer, adjacent to which the unidirectional Runway 14/32 will be constructed, is approximately 7,200 feet. The Runway itself will be 5,000 linear feet long, with a 1,000-foot runway safety area at each end. Construction work, however, will not occur within the full area of the buffer zone over this entire length. These activities will be largely confined to areas landward of the existing perimeter road, which is generally located in the middle of the 100-foot buffer zone. Once re-graded, the disturbed areas will be stabilized with grasses common to the airfield. Portions of the buffer zone that are presently paved will be converted to grass. Construction of the runway and associated drainage system modifications are the only element of the improvements that may be subject to review under the MA Wetlands Protection Act.

Work within the buffer zone required to construct the runway will not alter the coastal bank or its function in terms of either storm damage prevention or flood control.

6.5.3 Coastal Zone

Logan Airport is surrounded on three sides by Boston Harbor. This location is within an area designated by the Commonwealth as the Coastal Zone.

6.5.3.1 Coastal Zone Management Program

The Preferred Alternative will have no direct or indirect impact on resource areas, public access, water-dependent businesses, recreation, or other maritime interests in the coastal zone. The Preferred Alternative is consistent with the 27 policies (regulatory and non-regulatory) of Massachusetts Coastal Zone Management (CZM) program, as documented in the following sections.

6.5.3.2 Consistency with Coastal Zone Management Policies

In accordance with state and federal regulations, construction projects within the Coastal Zone must be consistent with the policies and principles established for these areas by the Massachusetts Office of Coastal Zone Management (MCZM).

Accordingly, a review of the Preferred Alternative within the context of the Massachusetts Coastal Zone Management Program Federal Consistency Review Procedures (301 CMR 21.00) was conducted for this Supplemental DEIS/FEIR. A summary of the Preferred Alternative's consistency with each of the four MCZM policies and principles that are relevant to this project is provided below. It is anticipated that a description of the project's consistency will be submitted to MCZM for Coastal Zone Consistency Determination and review during this Supplemental DEIS/FEIR review period.

Water Quality Policy 1

Ensure that point-source discharges in or affecting the coastal zone are consistent with federally approved state effluent limitations and water quality standards.

Consistency: Airfield stormwater is presently directed by overland flow to the existing airfield drainage system for discharge via a series of outfalls to Boston Harbor. Airfield discharges to the Harbor currently meet Class SB water quality standards. The existing drainage system will be extended to receive runoff from new impervious areas associated with taxiway and runway construction. No new outfalls are anticipated, nor is any change in the characteristics of the runoff expected. Accordingly, the Preferred Alternative will be consistent with federally approved state effluent limitations and water quality standards. Drainage from portions of the airfield totaling approximately 55 acres will be redirected from the West Outfall to existing outfalls along Boston Harbor. A low-flow stormwater quality treatment device may be installed, if feasible, to handle drainage from paved sections of this 55-acre airfield area.

Habitat Policy 1

Protect coastal resource areas including salt marshes, shellfish beds, dunes, beaches, barrier beaches, salt ponds, eelgrass beds, and fresh water wetlands for their important role as natural habitats.

Consistency: The Preferred Alternative will not directly affect any coastal resource areas. Shellfish beds and salt marsh found around the airfield perimeter will be unaffected.

Although the pollutant loading may increase slightly due to the increase in impervious surfaces and runoff, the quality of runoff from the airfield is expected to remain the same. There is no indication that airfield runoff has any adverse impact on these resource areas. This is evidenced by the fact that shellfishing areas around Logan Airport's perimeter have been reopened for commercial harvesting over the past decade.

Public Access Policy 1

Ensure that developments proposed near existing public recreation sites minimize their adverse effects.

Consistency: There are several public recreation areas close to the airport including Constitution Beach in East Boston and several of the Boston Harbor Islands. The Preferred Alternative will not change the use of the airport and no new impacts to public recreation sites are expected as a result of the Preferred Alternative.

Growth Management Principle 2

Ensure that state and federally funded transportation and wastewater projects primarily serve existing developed areas, assigning highest priority to projects that meet the needs of urban and community development centers.

Consistency: The Preferred Alternative may be funded through a combination of federal and state money. Logan Airport is an existing developed area and improvement of the facility will meet the needs of urban and community development centers.

6.5.3.3 Coastal Barriers

The Airside Project must show compliance with the Coastal Barriers Resources Act of 1982, which generally prohibits development on undeveloped coastal barriers along the Atlantic and Gulf Coasts, as identified by the U.S. Fish and Wildlife Service (USFWS). The project site is not within the boundaries of a Federally defined coastal barrier. Therefore, the Preferred Alternative will have no impact on coastal barriers as defined by the Coastal Barriers Resources Act of 1982.

6.5.4 Wildlife Habitat

As described above, the grasses and other herbaceous species occurring in the infield areas serve as habitat for a variety of birds and mammals. Conversion of these areas to paved surface will reduce available habitat areas. Upon the completion of construction and re-vegetation of disturbed areas under the Preferred Alternative, approximately 440 acres of vegetation will remain on the airfield. Consequently, proposed airside construction activities are not anticipated to result in modifications to the wildlife species composition of the Logan Airport airfield. Several of the infield areas currently serve as habitat for the upland sandpiper (*Bartramia longicauda*). Impacts to this state-listed endangered species are presented in Section 6.5.5, below.

6.5.5 Endangered and Threatened Species of Flora and Fauna

No Federal-listed endangered or threatened species are known to occur on the Logan Airport airfield. Accordingly, no impacts to federal-listed endangered or threatened species are anticipated with construction of the Preferred Alternative.

6.5.5.1 Impacts to State-Listed Species

The upland sandpiper, a state-listed endangered species, has been observed on the airfield in areas between runways and taxiways where improvements are proposed. Studies conducted in 1996 for this project identified one confirmed and three suspected nesting locations for the upland sandpiper, all in the infield areas between Runways 4L / 22R and 4R / 22L. The confirmed location was positioned in the infield area between Runways 4L / 22R, 4R / 22L and Taxiways Charlie and Foxtrot. All suspected nesting locations were identified to the north of Runway 33L / 15R:

- Between the Runway and Taxiway Yankee;
- Between Runway 15L / 33R and Taxiway Romeo; and
- Between Taxiway Romeo and Taxiway N-3.

Based on observations by the Massport Wildlife Control unit in 1999, it is predicted that the upland sandpiper would continue to use some of these infield areas as nesting habitat during the nesting season.

Construction of Centerfield Taxiway will generally bisect three of these areas (see Figure 3.1-1), avoiding disturbance of the area between Taxiway Romeo and N-3. Mitigation measures associated with these impacts are presented in Section 6.5.5.2

Specifically, impacts to confirmed and suspected upland sandpiper habitat, based upon field observations conducted in 1996, will be a maximum of approximately 37 acres. This represents the total area of existing mowed grassland that will be converted to paved area as a result of the construction of Centerfield Taxiway and the Taxiway Delta extension. Other areas of pavement will be added in areas that are not presently grassland and are not known to support upland sandpiper habitat. No grassland areas that are known to support upland sandpiper will be affected by construction of proposed unidirectional Runway 14 / 32. In addition to the direct loss of habitat, construction of the Centerfield Taxiway also will reduce the size of contiguous grasslands on either side of the Centerfield Taxiway. However, the remaining grassland areas will still be available as upland sandpiper habitat once construction is completed and the areas are revegetated.

6.5.5.2 Upland Sandpiper Mitigation Plan

Construction of the Centerfield Taxiway is proposed in mowed grassland areas of the airfield, which have been documented to support breeding and nesting habitat for the upland sandpiper (*Bartramia longicauda*), a state-listed endangered species. In addition, extension of Taxiway Delta also will be constructed in a mowed grassland area of the

airfield. Although no breeding or nesting habitat areas have been documented recently in areas to be affected by the Taxiway Delta extension, studies in 1990 conducted for the Central Artery/Tunnel project identified this location as potential habitat at that time.

Collectively, construction of the Centerfield Taxiway and the Taxiway Delta extension will result in the conversion of approximately 37 acres of existing grassland to paved surface. This conversion will eliminate this 37 acres as potential habitat for the upland sandpiper.

According to the MA Natural Heritage and Endangered Species Program (NHESP), proposed airside construction activities and the resultant loss of endangered species habitat constitute a "taking" as defined under the Massachusetts Endangered Species Act (MGL c.l3lA, MESA). In accordance with 321 CMR 10.04(3)(b), prior to a "taking, " a Conservation and Management Permit must be issued. Issuance of a Conservation and Management Permit is contingent upon demonstrating that: (1) "an insignificant portion of the local population will be impacted or no viable Alternative for the proposed project or activity exists; " and (2) "a conservation plan, submitted to and approved by the Director [Division of Fisheries and Wildlife], will be carried out that provides a long-term net benefit to the conservation of the local population of the impacted species." Coordination on the MESA process is handled by NHESP.

The following sections describe the project's compliance with elements of MESA and discuss mitigation measures proposed with the intent of providing a "long-term net benefit to the conservation of the local population of the impacted species." As described below, Massport has worked closely with NHESP in the development of the Conservation and Management Plan component of the mitigation program.

Impacts on the Local Population

There will be no direct project impacts to any upland sandpipers. This will be ensured through implementation of a two-part mitigation program. The first part of this program involves the enhancement of grassland habitat elsewhere on the airfield early in the construction season, prior to the spring arrival of the upland sandpiper population, to encourage the occupation of these areas, rather than construction areas. In addition, Massport will implement a rigorous pre-construction reconnaissance of the affected areas to ensure that no upland sandpipers remain in the area. Details of these mitigation elements are provided below as part of the proposed Conservation and Management Plan.

While the successful implementation of these two elements of the program will avoid direct impacts to individual birds, existing habitat areas will be disturbed and permanently lost as habitat. According to NHESP, this is considered to be an impact on the local population.

Alternatives for the Proposed Project

Construction of the taxiway improvements are directed at: (1) alleviating specific existing airfield layout deficiencies which result in taxiway congestion and delay; (2) improving overall airfield operating efficiency; and (3) enhancing safety.

In the context of MESA, Alternatives are considered to be project options that would avoid impact to the affected species. Because of the existing arrangement of runways and taxiways at Logan Airport and FAA siting requirements, opportunities to reconfigure or relocate taxiway improvements and still meet the project purpose and need do not exist. For example, there is no other location on the airfield to construct a north/south taxiway to serve Runways 4L/22R and 4R/22L. Its position between the runways is driven by FAA design criteria based upon the type of aircraft operations on the runways. Based on these design parameters, the taxiway must be offset a minimum of 400 feet from the centerline of either of the adjacent parallel runways. In addition, consideration was given to intersections with existing runways and avoidance of existing navigational equipment. As such, there is little opportunity to move the position of the Centerfield Taxiway in any manner that would significantly minimize impacts to upland sandpiper habitat.

Proposed Conservation and Management Plan

Insofar as impacts to upland sandpiper habitat have been identified and no viable Alternative for the proposed project exists, a Conservation and Management Plan has been developed to provide a long-term net benefit to the conservation of the local population of the upland sandpiper. It is important to understand that a primary consideration in development of the Plan is the continuation or enhancement of aviation safety. In this manner, the Plan strives to encourage the use of alternate areas on the airfield without encouraging new aviation hazards. Based on discussions and coordination with NHESP, the Plan is composed of three elements. These three elements involve:

- Alteration of existing airfield grassland mowing procedures to encourage upland sandpipers to use non-construction areas;
- Implementation of a pre-construction and an on-going pre-mowing upland sandpiper reconnaissance program; and
- Off-site mitigation.

Details of each of these plan elements follow.

Alteration of Existing Airfield Grassland Mowing Procedures

Previous studies and anecdotal observations indicate that upland sandpipers prefer areas of taller vegetation for nesting, commonly locating their nests within tufts of grass beneath the overhanging blades (Buss and Hawkins, 1939; Johnsgard, 1981; DeGraf and Rudis, 1986). While nests located in mowed fields have been reported, these sites were not regarded by any author as preferred habitat. Buss and Hawkins (1939) did report a

preference for loafing grounds with low tussocks and sparse vegetation no taller than the bird's back (approximately 9 inches). These reports are consistent with the observations made at Logan Airport in 1990 and 1996.

As described above, in maintaining the airfield, Massport's primary goal is aviation safety. With regard to avian species, this translates to an objective of discouraging flocking (e.g., starlings) and certain larger birds (e.g., gulls), which are a documented aviation hazard. The current infield management practice at Logan Airport consists of periodic mowing of all grassed areas in a rotation, such that continuous mowing is sufficient to maintain safe conditions throughout the growing season.

Safe conditions comprise vegetation heights and densities low enough to retard insect and rodent populations, and discourage feeding by bird species that present a threat to aviation safety. Since 1991, the FAA has recorded four documented upland sandpiper aircraft strikes. One of these events (Philadelphia, 11/30/92) was reported to have disrupted operation of one aircraft engine. More recently, an upland sandpiper aircraft strike involving a Delta 737 was documented at Logan Airport on August 13, 1997.

Over the past 3 to 4 years, the mowing rotation has begun with the cutting of perimeter areas, followed by mowing of the infield areas, with the area between Runways 4L/22R and 4R/22L mowed last. This sequence is followed specifically to avoid or minimize impacts to the upland sandpiper. When the areas between Runways 4L/22R and 4R/22L are mowed, maintenance personnel mark nest sites as they become aware of them and postpone mowing in their immediate vicinity until the end of the nesting season. In 1996, one confirmed and two suspected nesting areas were identified in this area. No other nesting areas on the airfield were found.

Following this mowing sequence, suitable nesting conditions remained between Runways 4L/22R and 4R/22L throughout much of the upland sandpipers' nesting period. Other areas of the airfield that were mowed earlier appear to have been not favored by the upland sandpiper.

Based on these findings and an understanding of the species' habits, it appears that the height of grasses at the initiation of nesting, rather than any specific location, is more critical for the selection of nest sites by the upland sandpiper. This suggests that with an alteration of the mowing sequence, other grassland areas of the airfield outside of high activity areas could serve as preferred nesting and breeding habitat.

Proposed Grassland Management Procedures

Both short-term and long-term mitigation measures are proposed relative to use of the airfield by upland sandpiper. Short-term measures will be implemented during construction of the Centerfield Taxiway and Taxiway Delta, while long-term measures will be integrated into Massport's continuing airfield maintenance program.

To encourage the use of alternate nesting areas for the upland sandpiper during periods of construction, the following management measures are proposed. Beginning in the spring prior to the start of construction (scheduled for 2002), the mowing schedule will be adjusted such that mowing begins in the area of the proposed Centerfield Taxiway, while designated alternate infield areas (between Taxiways Charlie and Foxtrot, and Charlie and Runway End 33L) remain unmowed until the end of the mowing rotation. Except as noted below, the area between Runway End 27 and Runway End 33L will not be placed in the mowing rotation until after the fledging of upland sandpiper chicks. This area has previously, but does not presently, support upland sandpiper nesting. In this area, prior to fledging, mowing will be limited to a perimeter strip directly adjacent to the runways and taxiways. These alternative nesting areas will provide greater protection to birds by reducing the likelihood of mortality, and may enhance reproductive success by providing a greater separation between nesting areas and active runways.

Post-construction, infield areas adjacent to the Centerfield Taxiway will once again be shifted to the end of the mowing rotation, consistent with existing practices. As always, however, the mowing sequence will depend upon wind and weather conditions, which dictate active runway usage. Two of the alternate infield areas will be mowed following mowing operations adjacent to Centerfield Taxiway. As part of the long-term management program, the infield area between Runway Ends 27 and 33L will only be mowed following upland sandpiper fledging. As is the current procedure, Massport preserves the right to amend the mowing protocol to meet operational requirements or if the proposed mowing schedule is found to compromise aviation safety. The NHESP would be notified prior to implementation of any long-term modifications of the mowing program.

Construction Period and Ongoing Grassland Reconnaissance

Prior to and during construction, a systematic reconnaissance will be conducted by Massport in all infield areas to be mowed throughout the nesting season to identify the locations of active nests. This search will focus on infield areas for which there is a historic record of upland sandpiper nesting. If active nests are encountered within other areas, these locations will be added to the areas to be checked. Once identified, nest areas will be marked in the field, and mowing in the vicinity postponed until after the fledging period. Through this process of active reconnaissance prior to mowing, there will be an additional level of protection for the local population over that which exists presently. Annually thereafter, bird reconnaissance will be conducted prior to mowing to provide a continued level of protection to breeding and nesting upland sandpipers.

Offsite Mitigation

While relocation of the existing population of upland sandpiper to other areas of the airfield is viable, enhancement of bird habitat at Logan Airport is not feasible due to the significant potential of increased aviation safety hazards and hazards to the birds. Such relocation does not constitute a “net benefit to the local population”, and accordingly the NHESP directed Massport to consider off-site mitigation to supplement the on-site mitigation. NHESP has identified Eastern Massachusetts as the range of the upland sandpiper local population.

Massport has worked closely with the NHESP on a program to provide a net benefit to the local population of upland sandpiper. This program would fund the restoration of a parcel of previously high quality grassland habitat at Camp Edwards on the Massachusetts Military Reservation on Cape Cod. This area is on a portion of Camp Edwards known as the cantonment area.

The cantonment area, a former military parade ground, supported a substantial population of upland sandpiper as recently as the mid-1990's. Since that time, there has been a gradual succession of this site from grassland to that of scrub vegetation such as bayberry and larger woody vegetation, predominantly pitch pine and eastern red cedar. As a result, a substantial portion of the area has evolved into unsuitable upland sandpiper habitat, and that population had declined to only a few nesting pairs in 1999. Restoration of this area to grassland is fully consistent with the Massachusetts National Guard's (MNG) August 1999 *Draft Master Plan/Area-wide Environmental Impact Report*.

To restore this area to grassland, in particular Little Blue Stem grass (*Schizachyrium scoparium*), Massport would fund a program to remove all existing shrub and woody vegetation down to a height that can be maintained by MNG using their existing mowing equipment. Wood chips and accumulated debris from the vegetation clearing operation will be removed to an offsite location. Clearing would be scheduled between September 1st and April 30th to avoid impacts to breeding birds.

To ensure the success of this program, Massport would make a one-time payment to fund any necessary vegetation removal by MNG during the season following the initial removal to maintain the site as Upland Sandpiper habitat. If necessary, selected areas that had a dense overstory and limited groundcover would be reseeded using native seed stock. A Memorandum of Understanding (MOU) between Massport and MNG to ensure implementation of the program is anticipated.

It is also anticipated that the MNG will commit to a grassland management plan previously developed for the cantonment area by NHESP (*Rare Grassland Birds and Management Recommendations for Camp Edwards / Otis Air National Guard*, NHESP, 1995) once Massport has funded restoration of the area.

In general, the NHESP grassland management plan presents the following recommendations to maintain or enhance habitat for rare grassland birds in the cantonment area at Camp Edwards:

- Restrict mowing between May and July to protect nesting and breeding birds
- Periodically mow areas to provide a diversity of grass height (3-12") and prevent encroachment of woody vegetation
- Restrict use of the area during the breeding season

In the event that such a restorations program at Camp Edwards is not possible, an appropriate alternative program, agreeable to the NHESP, will be developed and implemented.

6.6 Water Resources

The anticipated construction and operation impacts of the Preferred Alternative with regard to water resources are described in the following sections. Construction of the airside taxiway and/or runway improvements comprising the Preferred Alternative will change the total area of impervious surface on the airfield. Although there will be a net increase airfield-wide in impervious surface with all build Alternatives, there will be a net gain in pervious/grassed areas in several of the airfield subdrainage areas due to the removal of pavement in some areas. The addition of impervious area will result in a slight increase in the peak volume of runoff to Boston Harbor. Through the use of grassed swales and infiltration and low-flow stormwater quality treatment devices, increases in peak discharges will be minimized. Since fueling and maintenance do not occur on areas of the airfield where construction is proposed, a change in the quality of the runoff is not anticipated.

6.6.1 Volumetric Impacts to Water Resources

Construction of the runway and taxiway improvements under the Preferred Alternative will result in an increase of impervious surfaces, totaling approximately 37 acres or approximately 3.8 percent. The anticipated quantitative changes in runoff for the Preferred Alternative are summarized in Table 6.6-1.

Due to the dampening effect the incoming tide produces on the flow of stormwater through the airfield drainage system, the additional impervious surfaces will result in approximately a 3.8 percent increase in the peak rate of runoff. Water which is not evapo-transpired from presently vegetated areas will infiltrate the ground, and eventually discharge to Boston Harbor. There will be little to no measurable net change in airfield hydrology.

Table 6.6-1
Changes In Runoff Volume for the Preferred Alternative

Construction Element	Area of Pavement (acres)	Runoff (cubic feet)
Existing Airfield	990	150,072,912
Unidirectional Runway	+2.7	409,290
Centerfield Taxiway:		
North of 15R/33L	+16.8	2,551,240
South of 15R/33L	+13.3	2,022,195
Taxiway November Realignment	-1.6	-250,122
Taxiway Delta Extension	+7.5	1,138,432
Southwest Corner Optimization	-1.1	-169,779
Net Change	+37.6	+5,701,255
Percentage Change	+3.8%	+3.8%

LEGEND

● Major Outfall

massport

Figure 6.6-1

Proposed Drainage Areas

7466-FIG-6.2-1.p65

The new runoff will be conveyed through existing and new sections of drainage pipe to the existing drainage system outfalls. No new outfalls will be required to support the Preferred Alternative improvements. However, several areas of airfield drainage will be redistributed to other existing outfalls. A conceptual layout of the reconfigured stormwater drainage areas is provided in Figure 6.6-1.

6.6.2 Impacts to Water Quality During Construction

The potential exists for temporary increases of suspended solids due to unavoidable siltation while presently paved and/or vegetated soils are removed and replaced by new vegetation and pavement. Extensive siltation controls will be installed and maintained during all portions of construction to minimize adverse water quality impacts. Construction will be phased to minimize the areal extent of bare soil at any one time. Construction phasing and mitigation measures are described in Section 6.9.

6.6.3 Impacts to Water Quality During Airport Operations

Changes to water quality during airport operation once the Preferred Alternative is in place will be minimal. Any incremental changes in impact would result from runoff from new taxiway and runway pavement and the normal airfield activities associated with aircraft departures and arrivals, as well as wintertime deicing.

As illustrated in Figure 6.6-1, there will be some reconfiguration of the airfield drainage patterns. The reconfiguration will redirect some drainage in the southwest corner of the airfield away from the West Outfall into existing airfield perimeter outfalls A-41, A-42 and A-43. Presently, the West Outfall handles stormwater flows from the terminal, apron and fueling areas of the airport in addition to portions of the airfield. The West Outfall is equipped with an oil/water separator for treatment of the flows from the terminal, apron and fueling areas.

Stormwater to be redirected away from the West Outfall Runoff to the perimeter outfalls consists of flows from the airfield, including runways, taxiways and grassed infield areas. These portions of the airfield do not generate significant concentrations of contaminants. However, rather than discharging stormwater from these watersheds directly to the Harbor, Massport will install a low-flow water quality treatment structure to collect runoff from the first stormwater flush of these paved areas. The treatment device will be an off-line structure that would treat the first flush while allowing larger storms to by-pass the structure. The pollution prevention device would remove any sediment and floatables from the first flush and store them for subsequent removal and disposal.

Because the drainage system for the West Outfall includes the majority of the terminal area plus some taxiways and runways, this redirection of runoff will reduce the hydraulic load on the existing pollution control facility for the West Outfall. This will enhance its performance by reducing the volume of diluting taxiway and runway runoff that are minor sources of pollutants. All stormwater from fueling and maintenance areas will continue to

pass through the existing West Outfall pollution control facility. As stated previously, no fueling occurs in areas of the airfield where construction is proposed.

Therefore, although the pollutant loading to the harbor may be increased slightly as the result of deicing Runway 14/32, the general quality of runoff from the airfield is expected to be similar to present runoff, as previously discussed in Section 5.6 and shown in Table 5.5-1 of the Airside Project Draft EIS/EIR. Operation of the low flow stormwater quality treatment device is expected to minimize potential adverse water quality impacts to the maximum extent practicable. The data indicate that the existing airfield runoff meets the DEP's Class SB water quality standards. Because aircraft operations are expected to be more efficient, resulting in shorter taxiing times, the contribution of aircraft pollutants is expected to be reduced as well.

6.6.4 Consistency with DEP Stormwater Management Policies

Construction of the runway and/or the taxiway improvement components of the Preferred Alternative will require work within the 100-foot buffer zone as defined under the Massachusetts Wetlands Protection Act (see Section 6.5.2). Work within the buffer zone or associated resource areas is now subject to the DEP's Stormwater Management Policy and associated performance standards. A series of nine performance standards have been established. All new runway/taxiway construction within areas subject to the Stormwater Management Policy will be required to meet or exceed all applicable policies. Each of the policies are summarized below, together with a discussion of the project's compliance with each of the nine policies.

Policy 1

No new stormwater conveyances (e.g., Outfalls) may discharge untreated stormwater directly to or to cause erosion in wetlands or waters of the Commonwealth.

Consistency. The Preferred Alternative does not include any new or resized outfalls. Runoff from new paved areas will be handled through modifications to the existing airfield drainage system that result in better utilization of outfalls that are currently under capacity. A low flow stormwater quality treatment device may be installed to treat first-flush drainage from portions of the airfield drainage being redirected away from the West Outfall.

Policy 2

Stormwater management systems must be designed so that post-development peak discharge rates do not exceed pre-development peak discharge rates.

Consistency. Not applicable. The Preferred Alternative will continue to discharge to tidal waters. As stated in the DEP's Explanation of Standards, on Page 1-5 of the Stormwater Policy Handbook, discharges to waters subject to tidal action are not required to maintain pre-development peak discharge rates.

Policy 3

Loss of annual recharge to groundwater should be minimized through the use of infiltration measures to the maximum extent practicable. The annual recharge from the post-development site should approximate the annual recharge from the pre-development or existing site conditions, based on soil types.

Consistency. Because of existing soil conditions, the extent of paved surfaces, and the shallow depth of tidally influenced groundwater, the airfield does not serve as a groundwater recharge resource. The proposed construction and operation will not significantly alter site recharge characteristics.

Policy 4

For new development, stormwater management systems must be designed to remove 80 percent of the average annual load of total suspended solids (TSS).

Consistency. Existing airfield runoff data indicate an average suspended solids concentration of approximately 11 mg/l, or less. Massport will install a low flow stormwater quality treatment device to handle first-flush drainage from paved areas where flow is being directed away from the West Outfall. For other sections of the airfield, solids removal will be accomplished as stormwater is directed across grassed infield areas via overland flow to the drainage system.

Policy 5

Stormwater discharges from areas with higher potential pollution loads require the use of specific stormwater Best Management Practices (BMPs). The use of infiltration practices without pretreatment is prohibited.

Consistency. Massport currently employs a range of BMPs in the operation of the airfield. Elements of these procedures include maintenance of stormwater catchbasins, inspection of the stormwater collection system, specified areas for vehicle maintenance, maintenance of spill reporting log, among other measures. The airfield is not considered a generator of higher pollutant loading.

Policy 6

Stormwater discharges to critical areas must utilize certain stormwater management BMPs for critical areas.

Consistency. All new stormwater drainage system components in areas of new runway and/or taxiway construction will be operated and maintained in accordance with Best Management Practices.

Policy 7

Redevelopment of previously developed sites must meet Stormwater Management Standards to the maximum extent practicable.

Consistency. Airfield redevelopment will meet the Stormwater Management Standards to the maximum extent practicable.

Policy 8

Erosion and sediment controls must be implemented to prevent impacts during construction or land disturbance activities.

Consistency. A site-specific comprehensive erosion and sediment control plan will be developed for implementation until disturbed areas are stabilized, to prevent impacts during construction. No discharge will be made to critical areas.

Policy 9

All stormwater management systems must have an operation and maintenance (O&M) plan to ensure that systems function as designed.

Consistency. New components of the stormwater drainage system will be operated and maintained in accordance with current airfield stormwater management Best Management Practices included in the draft Stormwater Pollution Prevention Plan (SWPP) developed as part of Logan Airport's NPDES permit application.

6.7 Soils/Sediment Impacts

This section contains information on soil-related activities associated with the proposed construction of the Preferred Alternative. Construction will not take place in Boston Harbor and therefore impacts from the disturbance of marine sediment are not present.

Disposal of soils excavated for runway and taxiway construction will therefore be regulated under the Massachusetts Contingency Plan (MCP) (310 CMR 40.0000) and will be managed in accordance with a project-specific Soil Management Plan. A discussion of the MCP and the Soil Management Plan is provided in the following sections.

6.7.1 Massachusetts Contingency Plan (MCP)

The purpose of the MCP is to "provide for the protection of health, safety, public welfare, and the environment" by instituting a uniform mechanism for identifying contaminated soils and groundwater and implementing appropriate corrective actions.

In terms of soil excavation, excess excavate from construction must be managed appropriately. Soils are termed "non-remediation wastes," if the constituents in the soil do not trigger the notification requirements for the site specific "site activities and uses." If the opposite is true and the contaminant constituents trigger DEP notification, the materials are termed "remediation wastes." The MCP procedures for the management of remediation wastes are at 310 CMR 40.0030.

The Soil Management Plan developed by Massport for construction projects at Logan Airport, which are described below, is consistent with the MCP and dictates how excess excavate will be reused, recycled or disposed.

6.7.2 Massport Soil Management Plan

For Logan Airport construction projects, Massport developed a Soil Management Plan which dictates specific requirements to which contractors must adhere to in determining the chemical characteristics of excavation materials and determine how the materials should be reused, recycled and / or disposed. Those same criteria will be applied in the Airside Project.

Massport's Soil Management Plan was adopted using a conservative approach to protect environmentally sensitive areas. The MCP (310 CMR 40.0000) contains criteria by which one can determine appropriate soil disposal conditions and / or locations, consistent with land use receptor characteristics as identified in Table 40.933(9) of the MCP. Massport has taken the conditions allowed within the MCP and adopted a more stringent approach that no excavation materials from Logan, no matter what the characterization results, will be disposed at sensitive areas such as residential, recreational or wetland areas.

The Massport Soil Management Plan considers soil to be either unregulated or regulated as follows:

- **Unregulated soils** are those soils having chemical concentrations equal to or of lower than the MCP Method 1 Risk Characterization soil standards for soil category S-1 and groundwater category GW-2 / GW-3. Unregulated soils may be used as backfill at Logan Airport or used off site on industrial sites where soil quality concentrations are higher than the unregulated soil, and which may be capped with pavement or loamed and seeded. Unregulated soils cannot be disposed of in sensitive areas such as residential, recreational or wetland areas.

- **Regulated soils** are those soils having chemical concentrations which are equal to or greater than the MCP Method 1 Risk Characterization soil standards for soil category S-1 and groundwater category GW-2 / GW-3. Regulated soils may only be beneficially reused or recycled at Logan Airport if the contaminant concentrations are less than S-2 levels, or at off-site DEP, permitted facilities. They may also be disposed of out-of-state at similar facilities. Regulated soils cannot be disposed in sensitive areas such as residential, recreational or wetland areas.

This combination of S-1/S-2 GW-2/GW-3 categories is the simplest form of risk characterization and means that Massport has eliminated all residential, recreation, and wetland areas as possible disposal sites for excavation materials from Logan.

6.7.3 Construction Area Soil Sampling Program

Construction of Runway 14/32 and the taxiway improvement components as part of the Preferred Alternative will require the excavation of unsuitable or excess soils. Table 6.6-2 of the Airside Project Draft EIS/EIR estimated that approximately 537,000 cubic yards of soil would be excavated if all the improvement elements were constructed. The Airside Project Draft EIS/EIR assumed a uniform depth of excavation throughout the construction area to develop a worst-case estimate. As the concept design has evolved between the Airside Project Draft EIS/EIR and Supplemental DEIS/FEIR, the excavation requirements have been refined, resulting in a revised excavation requirement of approximately 264,000 cubic yards. Of this excavation volume, approximately 131,000 cubic yards of miscellaneous fill will be reused at locations along the airfield construction during the final grading for shoulders and other uses. There will be 83,500 cubic yards of excavated soil materials and 49,500 cubic yards of bituminous pavement removed from Logan Airport for reuse/recycling/disposal at permitted facilities. The difference in excavation volumes between the Airside Project Draft EIS/EIR (537,000 cubic yards) and the Supplemental DEIS/FEIR (264,000 cubic yards) is due to site-specific soil data that were obtained through a recent soil boring program for geotechnical and environmental information (See Section 5.7.1).

6.7.3.1 Unidirectional Runway 14/32

The soil pre-construction characterization data indicate that the soil under the footprint of the proposed unidirectional Runway 14/32 does not exceed the Reportable Concentrations for S-2 soil. Design information indicates that there will not be any excavation of the common borrow that was used to fill Bird Island Flats and which underlies much of the runway alignment. An estimated 82,000 cubic yards of soil will be excavated. Of this volume, approximately 37,000 cubic yards will be reused for surface grading.

6.7.3.2 Centerfield Taxiway

Construction of the Centerfield Taxiway will require the excavation of approximately 52,000 cubic yards of soil material and the removal from the Airport of 11,000 cubic yards of existing fill. Approximately 41,000 cubic yards of soil will be reused. The soil pre-construction characterization data indicate that soil underlying the Centerfield Taxiway contains variable levels of contamination. The soil data indicate that no volatile compounds were present nor were any of the aliphatic fractions from the total petroleum hydrocarbon tests. The soil was found to exceed the S-2 Reportable Concentrations (RC S-2) for the polynuclear aromatic hydrocarbons, as determined in the EPH analysis. The PAH contamination was found from Taxiway Echo north to Taxiway Romeo. Beryllium

was the only priority pollutant metal to exceed the RC S-2. This condition was found adjacent to Runway 15L/33R and between Taxiways Echo and Charlie. Lead in the soil was found to exceed the 100 mg/Kg Toxicity Characteristic Leaching Procedure (TCLP) trigger level by a slight amount (110-120 mg/Kg) at three scattered locations. The TCLP test is one measure of the toxicity of a sample and upon exceeding regulatory limits it is determined to be TCLP hazardous. The results of the TCLP testing indicate that the soil did not exceed the TCLP regulatory limit of 5.0 mg/l for lead and is, therefore, not hazardous. The insecticide Dieldrin was found in the soil at eight locations. It is believed that the Dieldrin originated from historical mosquito control programs. The soil was found to not contain polychlorinated biphenyls.

6.7.3.3 Taxiway November Realignment

Soil underlying the area for the realignment of Taxiway November was found to be contaminated in excess of the Reportable Concentrations for S-2 soil with four polynuclear aromatic hydrocarbon (PAH) compounds and the insecticide Dieldrin. This contamination was only found in the surface soils (0-2 feet). The soil data indicate that no volatile compounds were present nor were any of the aliphatic fractions from the total petroleum hydrocarbon tests. Design information indicates that approximately 43,500 cubic yards of soil material will be excavated and 43,000 cubic yards of fill will be removed from Logan. Plans indicate that approximately 500 cubic yards will be reused onsite.

6.7.3.4 Southwest Corner Taxiway Reconfiguration

The soil sampling and analysis data indicate that the soil in the area of the Southwest Corner Taxiway Reconfiguration contains concentrations of four PAH compounds and the insecticide Dieldrin which exceed the Reportable Concentrations for S-2 soil. The soil data indicate that no volatile compounds were present nor were there any of the aliphatic fractions from the total petroleum hydrocarbon tests. Design information indicates that approximately 5,000 cubic yards of soil will be excavated and reused onsite.

6.7.3.5 Taxiway D Extension

The extension of Taxiway D will require the excavation of approximately 32,000 cubic yards of miscellaneous soil materials, all of which will be removed from the Airport except for 6,000 cubic yards reused onsite.

6.7.3.6 Massachusett Contingency Plan (MCP) Response Actions

As discussed in previous sections, certain contaminant concentrations were found to exceed the MCP Soil Category S-2 reportable concentrations resulting from a pre-construction characterization that was performed. As a result, Massport transmitted a Release Notification Form to DEP in January 2000. A Release Tracking Number (RN) of 3-19157 was assigned to the site by DEP. Through the performance of a Method 3 Risk Characterization, it was determined that certain concentrations of dieldrin in the vicinity of Sierra and Uniform

Taxiways and Runway 4R required remediation. Massport transmitted a Release Abatement Measure (RAM) Plan to DEP and subsequently removed the dieldrin source area. In January 2001, Massport transmitted a RAM Completion Report and Response Action Outcome. These documents state that a Condition of No Significant Risk to human health, safety, public welfare, and the environment exists at the site, and the conditions of a Class A-2 RAO have been met. No further MCP response actions are required.

6.7.4 Soil Management

The results of the soil pre-construction characterization program indicate that the soil underlying Runway 14/32 does not exceed the Reportable Concentrations for S-2 soil. Soil underlying the proposed construction areas for the Centerfield Taxiway, the realignment of Taxiway November and the Southwest Corner Taxiway realignment do exceed the Reportable Concentrations for S-2 soil. It is Massport's plan to reuse excavated soil on Logan Airport wherever feasible. Massport does not allow any soil from Logan Airport to be reused/recycled/disposed at sensitive off-site areas (near wetlands, drinking water supplies, and dwellings). Soil generated at Logan Airport may be reused in industrial sites as long as the soil is of comparable quality to the soil at the industrial site. Otherwise it must be disposed of at a state-approved lined landfill. In keeping with Massport's Soil Management Plan, the pavement will be either recycled at state approved in-state or out-of-state recycling facilities or disposed at approved in-state or out-of-state lined landfills.

6.8 Environmental Justice

The Environmental Justice analysis in the Airside Project Draft EIS/EIR was expanded for this Supplemental DEIS/FEIR. Noise was found to be the only adverse impact associated with the Preferred Alternative with the potential for environmental justice impacts. Additional demographic analyses of the noise-affected areas, as well as of the affected municipalities, were conducted to determine if minority and/or low-income populations would be disproportionately affected by the Preferred Alternative. This analysis found that there is no high and adverse disproportionate impact caused by the Preferred Alternative.

An additional area within the 65 dB DNL contour associated with the Preferred Alternative includes a predominantly Hispanic neighborhood in Chelsea that would experience an increase in noise of 0.6 dB DNL or less. Under FAA standards, this change is not a significant adverse impact (see discussion at Section 6.2.2.3). Moreover, mitigation of the increased noise will be provided to the affected community in the form of sound insulation. As a result, there is no disproportionate high and adverse impact on minority or low-income populations resulting from the Preferred Alternative.

As to the communities surrounding Logan, only 21 percent of the population within the 65 dB DNL contour is minority, compared to the Suffolk County minority population of 38 percent. Less than 2 percent of the population within the 65 dB DNL contour has a household income less than 150 percent of poverty level. The following sections provide a more detailed discussion of the environmental justice analysis of the impacts of the Preferred Alternative.

6.8.1 Introduction

The analysis of project impacts on minority and low-income communities that follows is conducted in accordance with federal Executive Order (EO) 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations, the National Environmental Policy Act (NEPA), and the Department of Transportation Order to Address Environmental Justice in Minority Populations and Low-Income Populations (Final US DOT Order).[12]

EO 12898, issued in 1994, requires "each Federal agency [to] make achieving environmental justice part of its mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations...." The U.S. Department of Transportation (DOT) published the Final US DOT Order in 1997,[13] setting forth a process by which DOT and its operating administrations will integrate the goals of EO 12898 with its existing regulations and guidance. The Final US DOT Order defines key terms, and provides guidance for identifying and addressing disproportionately high and adverse impacts to low-income and minority populations. Additional directives for implementing EO 12898 within the context of the NEPA process are provided by the Council on Environmental Quality (CEQ) in *Environmental Justice Guidance under the National Environmental Policy Act*.[14]

NEPA directs federal agencies to consider social, economic, and environmental factors in the evaluation of proposed actions. The Federal Aviation Administration has specified that environmental impact statements prepared for airports are to identify social impacts, such as community disruption, and identify the degree of impact and measures to minimize such impact.[15]

The May 7, 1999 EOEA Certificate Airside Project Draft EIS/EIR also directs Massport to provide the following information within the context of an environmental justice analysis: more detailed demographic data on the affected populations in both tabular and graphic form, analysis of the full range of impacts (including noise impacts within the 60 dB DNL contour), a comparison of the affected population with that of Boston and

15 FAA, October 8, 1985, *Airport Environmental Handbook*, Order 5050.4A.

the other affected municipalities, and a discussion of the community participation process used in preparing the Airside Project Draft EIS/EIR and Supplemental DEIS/FEIR.

6.8.2 Summary of Impacts of the Preferred Alternative

The following sections provide a summary of the environmental impacts of the Preferred Alternative as identified through the NEPA/MEPA environmental review process. For a more detailed discussion of each of these impact areas, refer to the appropriate section of this chapter. All impacts to biotic communities, water resources, and soils/sediments will occur on Massport property and will not affect adjacent communities within the study area.

6.8.2.1 Noise

The noise analysis is based on modeled noise impacts associated with the 29M Low Fleet scenario. This scenario presents the worst case for noise impacts in terms of the size of the noise-impacted population among all the alternative scenarios analyzed. All other scenarios show less noise impacts.

The established FAA threshold for adverse noise impacts in residential areas is 65 dB DNL. FAA Order 5050.4A, states "FAA's threshold of significance for noise impacts has been determined to be a 1.5 dB DNL increase in noise over any noise sensitive area located within the 65 dB DNL contour." Areas within the 60 dB DNL noise contour also were identified in accordance with the MEPA certificate.

Under the Preferred Alternative, unidirectional Runway 14/32 directs more airport noise over the water and allows for a more equitable distribution of aircraft operations consistent with PRAS goals. The Preferred Alternative results in a reduction of population exposed to DNL values greater than or equal to 70 and 75 dB DNL. These noise reductions benefit the communities that are currently most heavily impacted by noise—East Boston, Winthrop and Revere.

Under current conditions, Runway 15/33 is utilized significantly less than its intended utilization factor in accordance with the PRAS goals. This situation would be expected to continue without Runway 14/32. With Runway 14/32, Runway 15/33 will be able to be utilized at levels closer to those set out in the PRAS goals. (See discussion in Section 4.6.5.) The greater use of Runway 15R/33L in accordance with PRAS goals allowed by Runway 14/32 will result in a slightly larger population within the 65 dB DNL contour when compared to the No Action Alternative. The total population within the 65 dB DNL contour for the Preferred Alternative (29M Low Fleet scenario) is projected to be 17,894, an increase of 378 people (2 percent) when compared to the No Action 65 dB DNL population of 17,516.

According to the noise analysis conducted for this Supplemental DEIS/FEIR, the increase in noise levels is 0.6 dB or less in the area newly included within the 65 dB DNL contour under the Preferred Alternative. Under FAA's noise impact criteria, the increase in noise in these areas is not significant. Dwellings within these areas will become eligible for

sound insulation under FAA's criteria, and will be sound insulated as part of the Preferred Alternative. (See Chapter 8 for a discussion of mitigation commitments.)

Implementation of the Preferred Alternative is expected to produce a reduction in ground taxi noise at the following noise monitoring stations:

- Loring Road at Court (#7), Winthrop;
- Bayswater and Shawsheen (#10), East Boston;
- East Boston Yacht Club (#12);
- Somerset and Johnson (#6), Winthrop;
- Jeffries Point Yacht Club (#14), and
- Sumner Street near Lamson (A), East Boston.

Therefore there are no adverse ground noise impacts associated with the Preferred Alternative.

6.8.2.2 Land Use

The Preferred Alternative involves operational and construction improvements to reduce delay and enhance safety at Logan, and is restricted to activities and purposes compatible with normal airport operations and existing land use plans. The noise analysis indicates that the Preferred Alternative will reduce noise in areas with the highest noise impacts, but will slightly increase the population within the 65 dB DNL contour, when compared to the No Action Alternative.

All construction will occur on the existing airfield. There will be no displacement or relocation of any residential housing, community institutions or off-airport businesses as a result of implementation of the Preferred Alternative. The only relocation required is for the commercial tenants of Building 60 in the South Cargo area of the airport, and relocation assistance as required under state and federal law will be provided to mitigate this impact. A more detailed discussion of land use impacts is provided in Section 6.3.

6.8.2.3 Air Quality

Due to improved airfield efficiency and shorter delay periods, the Preferred Alternative is projected to result in a slight reduction of emissions of air pollutants when compared to the No Action Alternative. The increased use of Runway 15/33 under Preferred Alternative does not result in an adverse air quality impact as modeled at the Eagle Hill receptor site located in East Boston at the Runway 15 end. Ambient levels of air pollutants at the Eagle Hill receptor site, as well as throughout the study area, are expected to be well within ambient air quality standards and guidelines under all future fleet scenarios. Therefore, there are no adverse air quality impacts associated with the Preferred Alternative.

6.8.2.4 Construction

Construction of the runway and taxiway improvements will occur on the existing airfield. Construction will be managed to minimize air, noise and other impacts to the adjacent community. All construction vehicles will be required to access Logan Airport via Route 1A or the Ted Williams Tunnel on designated haul routes. Construction traffic will be kept on Logan Airport roadways or the state highway system and will not be allowed on local community streets, except for a short section of Neptune Road for access to the north construction gate. A more detailed discussion of construction impacts is provided in Section 6.9 of this Supplemental DEIS/FEIR**.**

An analysis of construction noise impacts indicates that the noise increases projected as a result of construction range from 0 dBA to 0.8 dBA with respect to the ambient level. Based on Federal Highway Administration criteria that categorizes less than a 5 dBA increase as 'no impact,' no construction noise impact is predicted at any off-airport residential sites. Therefore, there are no adverse construction impacts associated with the Preferred Alternative.

6.8.3 Methodology and Key Definitions

6.8.3.1 Methodology

The analysis of impacts conducted for this Supplemental DEIS/FEIR identified noise as the only off-site environmental impact associated with the Preferred Alternative with the potential to cause disproportionately high and adverse health or environmental effects on minority and/or low-income populations. The environmental justice analysis which follows therefore assesses the potential for disproportionate noise impacts to low-income and minority populations.

The data presented are based on 1990 U.S. Census Data[16] using Geographic Information System (GIS) technology to analyze impacts at a Census Block level where the data are available. The "Block" represents the most detailed level of census data. In addition, the estimates of 1995 population (total and minority) for all cities and towns in Massachusetts, developed by the Massachusetts Institute for Social and Economic Research (MISER), were reviewed. No comparable estimate of 1995 low-income population was available. The 1995 population estimates are not available at a Block Group level and therefore were not used to update this analysis. Nonetheless, the 1990 Census Block data were compared to the 1995 population estimates to assure that there are no meaningful differences in the data relevant to the environmental justice analysis (See Table 6.8-1).

16 The U.S. Bureau of the Census conducted the most recent decennial census in the spring of 2000. Initial data on statewide population was released in December 2000. More detailed information from the 2000 decennial census will become available with the release of Public Law 94-171 in March 2001 and continuing throughout 2003. These initial data are redistricting data summary files at the block level with population totals, age of population 18 and older, and race/ethnicity that are released to the legislature and governors of each state. In mid summer 2001, household relationship, detail age and housing tenure data will be available. Detailed socioeconomic data will be released throughout 2002. Source: U.S. Department of Commerce, U.S. Census Bureau Website (www.census.gov), and U.S. Department of Commerce, U.S. Census Bureau Boston Regional Office, Verbal Communication with Tia Costello, January 08, 2001.

Table 6.8-1
1995 Estimate of Minority Population in Study Area Political Jurisdictions Affected by 65 dB DNL

City	Total Population	Percent Change from 1990	1995 Estimated Population by Race/Hispanic Origin: White[1]		Percent Change from 1990	Non-White[2] and Hispanic		Percent Change from 1990
Boston	564,328	-1.75%	314,687	(56%)	-7.87%	249,641	(44%)	6.30%

1 Not of Hispanic origin.
2 Includes all persons who indicated their race as African-American, American Indian, Asian or Pacific Island and Other Race.

The minority and low income populations within the 65 dB DNL contour as delineated by the Airside Project noise impact assessment were identified for the No Action Alternative and Preferred Alternative under the 29M Low Fleet scenario, which represents the highest impact scenario. The 65 dB DNL contour is the thresholds established by FAA for adverse noise impacts in residential areas. A similar analysis was developed for the population within the 60 dB DNL noise contour in accordance with the Massachusetts Secretary of Environmental Affairs' Certificate on the Draft Environmental Impact Report.

The characteristics of the population within the 60 and 65 dB DNL contours were also compared to the characteristics of those political jurisdictions affected by these noise contours. The political jurisdictions affected by the 65 dB DNL contour include the Cities of Boston, Chelsea and Revere, and the Town of Winthrop, which collectively comprise Suffolk County. The City of Everett is added to the above list for communities affected by the 60 dB DNL contour.

Analysis conducted for the Airside Project Draft EIS/EIR first identified census blocks that were 50 percent or more minority, and then counted the total population within those blocks to determine the minority population. Low-income populations were identified by the median income for the census block group. The entire population of the block group was considered to be low-income if the median household income for the block group was at or below the identified poverty level. A combined total of the minority and low-income populations was reported in the Airside Project Draft EIS/EIR.

A more detailed demographic analysis was conducted for this Supplemental DEIS/FEIR, the results of which are described below.

All minority individuals for the census blocks within the 60 and 65 dB DNL noise contours were identified from the 1990 census data. The minority population presented in this Supplemental DEIS/FEIR represents the total minority population within the identified noise contours. The methodology to identify low-income populations was the same for both the Airside Project Draft EIS/EIR and this Supplemental DEIS/FEIR. Low-income populations were identified by the median income for the census block group. The entire population of the block group was considered to be low-income if the median household income for the block group was at or below the identified poverty level. An additional level of analysis was conducted in this Supplemental DEIS/FEIR to identify the population at 150 percent of the federal poverty level. This Supplemental Draft EIS/Final EIR presents the minority and low-income populations separately, instead of as a combined total as was done for the Airside Project Draft EIS/EIR analysis.

6.8.3.2 Definitions

Minority Population

A minority person is defined as an individual who is a member of one of the following population groups: Black (not of Hispanic origin), Hispanic, Asian, and American Indian or Native Alaskan. According to the Final US DOT Order, a minority population means any readily identifiable groups of minority persons that live in geographic proximity. CEQ Guidance states that minority populations should be identified where either (a) the minority population of the affected area exceeds 50 percent, or (b) the minority population percentage of the affected area is meaningfully greater than the minority population percentage in the general population or other appropriate unit of geographic analysis. Information on race and Hispanic origin was analyzed at the Block Level utilizing the 1990 U.S. Census, which is the most detailed level of population data made available by the U.S. Bureau of Census.

Low Income

The Final US DOT Order defines low-income persons as those whose "median household income is below the United States Department of Health and Human Services poverty guidelines." CEQ Guidelines state that low-income populations should be identified with the annual statistical poverty thresholds developed by the Bureau of the Census. The Logan Airside Project improvements Planning Project used the 1990 U.S. Census as the data base for demographic analyses.

The federal definition of poverty level varies by size of family and number of related children under 18 years. Average poverty thresholds in 1990 ranged from $6,652 for one person, to $26,280 for households with nine or more family members**.** (See Appendix I.) According to the 1990 census, the average household size in Massachusetts is 2.68 persons, and in Suffolk County it is 2.51 persons. (Logan Airport and the majority of the study area

are located in Suffolk County.[17]) A family size of three therefore was selected as representative.

The population was considered to be a low-income population if the median household income was at or below $10,560. This represents the 1990 federal poverty level for a three-person household as defined by the U.S. Department of Health and Human Services.[18] In order to provide additional analysis of a broader range of incomes, the environmental justice analysis was also conducted using a median household income of 150 percent ($15,840) of the poverty level for a family of three. Information on income was analyzed at a Block Group level, the most detailed level of information available from the 1990 Census regarding income.

High and Disproportionate Adverse Impacts

Adverse impacts to low-income and / or minority populations are considered "high and disproportionate" if: (a) the adverse impact is predominantly borne by a minority population and / or a low-income population, or (b) the adverse impact that will be suffered by the minority population and / or low-income population is more severe or greater in magnitude than the adverse impact that will be suffered by the non-minority population and / or non-low-income population. The Final US DOT Order directs FAA to determine disproportionate impact, taking into account mitigation, enhancement measures and all off-setting benefits to the affected populations, as well as the design, comparative impacts and the relevant number of similar existing system elements in non-minority and non-low income areas.

6.8.4 Baseline Socioeconomic and Demographic Characteristics of Affected Jurisdictions

A determination of "disproportionately high and adverse impacts" to a low-income or minority population is based on a comparison of the impacts on these populations to the impacts experienced by the affected population as a whole. The Area of Potential Affect for the Logan Airport Airside Project improvements Project was identified as those political jurisdictions (cities and towns) affected by the 65 dB DNL contour, which is consistent with the federal definition of adverse noise impact contained in FAR Part 150. The potentially affected area for noise impacts was chosen to delineate the study area because noise is the most widespread impact. The population within the 60 dB DNL noise contour was also analyzed to be consistent with the MEPA Certificate on the Airside Project Draft EIS / EIR. The political jurisdictions affected by the 65 dB DNL contour include Boston, Chelsea, Winthrop and Revere, which collectively comprise Suffolk County. The City of Everett is added to this list of potentially affected communities under the 60 dB DNL noise contour. Tables 6.8-2 to 6.8-6 provide a summary of selected socio-economic and demographic characteristics of these communities. This information is used to provide a baseline against which to compare the characteristics of the population within the 65 and 60 dB DNL contours.

▼

17 Average household size was determined by dividing the number of persons by the number of households as provided in Landview III, which uses the 1990 U.S. Census as a database.

18 The 1999 poverty level for a family of three as report by the U.S. Department of Health and Services is $13,880.

1 Minority population calculated from two Census Categories: Persons by Race, and Persons of Hispanic Origin.

The 1995 population estimates indicate that population has declined in the City of Boston, and increased in the other communities, particularly in Revere and Chelsea. Overall the minority population within the study area has increased, while the white population has declined.

6.8.5 Analysis of Impacts to Minority or Low Income Populations

6.8.5.1 Impacts to Minority Populations

Under the No Action Alternative, the total population within the 65 dB DNL contour under the 29M Low Fleet scenario is 17,531. Of that total, approximately 79.4 percent of the affected population is white (non-Hispanic) and 20.65 percent of the affected population are members of a minority group. The population within the 65 dB DNL contour increases slightly (by 378 people) under the Preferred Alternative; however, the characteristics of the affected population are essentially the same. Of the total population of 17,909 within 65 dB DNL, 78.6 percent of the population is white (non-Hispanic) and 21.4 percent of the population is minority. The comparison indicates that under either Alternative, the affected population is predominately (79 to 80 percent) non-minority.

The Preferred Alternative allows noise impacts to be distributed more equitably across communities and over water in accordance with runway utilization goals that have been incorporated into PRAS. One of the primary goals of PRAS is to limit the number of people exposed to the highest noise levels (70 to 75 dB DNL). Implementation of unidirectional Runway 14/32 under the Preferred Alternative (29M Low Fleet scenario) reduces the noise-impacted population within 75 dB DNL from 257 to 77, a net reduction of 70 percent. The Preferred Alternative (29M Low Fleet scenario) also reduces the noise-impacted population within the 70 dB DNL contour from 1,521 to 1,459, a 4 percent reduction.

The difference in affected minority populations within the 65 dB DNL contour between the Preferred Alternative and the No Action Alternative is 0.9 percent. The percentage of the affected population within the 65 dB DNL contour for Preferred Alternative classified as minority (21.4 percent) is significantly lower than the percentage of the population of the affected jurisdictions (Boston, Chelsea, Revere and Winthrop) classified as minority (38 percent). This assessment still holds true assuming a 7.58 percent increase in the minority population within Suffolk County from 1990 to 1995 (See Table 6.8-4). An increase of this magnitude would increase the minority population within 65 dB DNL under Preferred Alternative from 3,834 (21.4 percent) to 4,124 (23.0 percent), which is still significantly lower than the 41 percent of the 1995 population of Suffolk County estimated to be minority. (See Tables 6.8-6 and 6.8-7 for a more detailed comparison of the affected population within the 65 dB DNL contour for the No Action Alternative and the Preferred Alternative, respectively.)

An area located in Chelsea added to the 65 dB DNL under the Preferred Alternative is inhabited predominantly by a Hispanic population. Approximately 227 minority residents within Chelsea will experience a noise increase of 0.6 dB or less. Sound insulation of the affected homes has been included as part of the Preferred Alternative to mitigate adverse noise impacts.

The noise effect of the Preferred Alternative does not represent an adverse impact to minority populations because it does not exceed the FAA threshold of significant impact (greater than a 1.5 dB change for populations within the 65 dB DNL). Moreover, overall airport noise does not represent a disproportionate impact to minority populations because only 21 percent of the population within the 65 dB DNL contour is minority compared to a 38 percent minority population for Suffolk County. In addition, the noise impact suffered by the minority population is not appreciably more severe or greater in magnitude than the adverse effect suffered by the non-minority population. In the 37M High Fleet scenario, the noise affected population of Chelsea is expected to be reduced. Finally, all noise impacts on Chelsea residents falling within the 65dB DNL noise contour will be mitigated with sound insulation.

1 Minority population calculated from two Census Categories: Persons by Race, and Persons of Hispanic Origin.

A similar conclusion can be reached when comparing the affected minority populations within the 60 dB DNL for the No Action Alternative and the Preferred Alternative. The affected population within 60 dB DNL is predominately white (Non-Hispanic) for No Action Alternative (79.3 percent) and for Preferred Alternative (78.9 percent). The percentage of the affected population within 60 dB DNL classified as minority is essentially the same; 20.7 percent for No Action Alternative and 21.1 percent for Preferred Alternative. In addition, the percentage of the affected population within the 60 dB DNL contour for Preferred Alternative classified as minority (21.1 percent) is lower than the percentage of the population of affected jurisdictions (Boston, Chelsea, Everett, Revere, and Winthrop) classified as minority (38 percent). Tables 6.8-9 and 6.8-10 provide a more detailed comparison of the affected population within the 60 dB DNL contour for the No Action Alternative and the Preferred Alternative, respectively.

Figure 6.8-1 illustrates the relationship of the 60 and 65 dB DNL noise contours for the No Action Alternative and the Preferred Alternative to the minority populations within the communities adjacent to Logan.

6.8.5.2 Impacts to Low-Income Groups

There are no low-income populations within 75 dB DNL or 70 dB DNL under either the No Action or the Preferred Alternatives.

Implementation of the Preferred Alternative would not have a significant impact on low-income populations, since 98 percent of the affected population within the 65 dB DNL contour has a household income greater than $15,840 (150 percent of the federal poverty level). The total population within the 65 dB DNL contour under the 29M Low Fleet scenario with a household income of less than $10,560 is 18 persons for both the No Action Alternative and Preferred Alternative, which represents 0.1 percent of the total affected population. The affected population with household incomes less than $15,840 increases slightly under Preferred Alternative to 1.9 percent, but is still a very small percentage of the affected population as a whole. Both percentages are

significantly lower than the percentage (18.1 percent) of the population of Suffolk County below the poverty rate. (See Tables 6.8-6 and 6.8-7 for a more detailed comparison of the affected low income population within the 65 dB DNL contour for the Preferred and No Action Alternatives, respectively.)

A similar conclusion can be reached when comparing the affected low-income populations within the 60 dB DNL contour for the No Action and Preferred Alternatives. Approximately 0.07 percent of the affected population within the 60 dB DNL contour for No Action Alternative has a household income of less than $10,560. This increases slightly to 0.9 percent of the population for the Preferred Alternative primarily due to the inclusion of the institutional population on Long Island within the 60 dB DNL contour. The percentage of the affected population within 60 dB DNL with household incomes less than $15, 840 is 8.0 percent for the No Action Alternative and increases slightly to 10.1 percent for the Preferred Alternative. These percentages of low-income populations within the 60 dB DNL contour for the Preferred Alternative are lower than the percentage of the population of affected jurisdictions (Boston, Chelsea, Everett, Revere, and Winthrop) classified as below the poverty level (See Table 6.8-1) (See Tables 6.8-9 and 6.8-10 for a more detailed comparison of the affected low income population within the 60 dB DNL contour for the No Action Alternative and Preferred Alternatives, respectively).

The noise effect of the Preferred Alternative does not represent a disproportionate impact to low income populations because it is not predominately borne by that population. The environmental justice analysis indicates that the population within the 65 dB DNL contour is not predominately low-income. Less than 0.1 percent of this population is at poverty level ($10,840), and only 1.9 percent have incomes below 150 percent of poverty level ($15,584) based on 1990 census data. (Estimates of 1995 income levels by community were not available.) In addition, the noise impact suffered by the minority population is not appreciably more severe or greater in magnitude than the adverse effect suffered by the non-minority population. There are no low-income populations within the 75 dB DNL and 70 dB DNL contours under the Preferred Alternative.

Figure 6.8-2 illustrates the relationship of the 60 and 65 dB DNL noise contours for the No Action and Preferred Alternatives to the low income populations within the communities adjacent to Logan.

6.8.5.3 Comparison of 1998 and No Action Alternative Noise Affected Population

The 1998 GEIR Annual Update presented noise contours for Logan Airport based on aircraft activity during 1998. In that year, the population within the 65 dB DNL contour was approximately 23,300. Comparison to the projected noise contour for the 29M Low Fleet scenario No Action Alternative shows a substantial reduction in the population exposed to 65 dB DNL. Under the 29M Low Fleet scenario No Action Alternative projections, total population exposed to 65 dB DNL or greater is approximately 17,500 persons, representing a 25 percent decline from reported 1998 levels.

The principal reason for this decline in overall airport noise impacts is the continuing phase out of noisier Stage 2 jet aircraft from the Logan Airport fleet. Secondarily, improved adherence to the Runway 27 ROD departure track will eliminate significant numbers of South Boston residents from the 65 dB noise contour. Both these developments are discussed in Chapter 5 of the 1998 GEIR Annual Update.

In addition to the predicted population reductions within the 1998 65 dB DNL contour that will occur as noted above, the Preferred Alternative will redistribute aircraft activity and their associated noise impacts over Boston Harbor. The proposed project will facilitate greater use of Runway 15R/33L in accordance with the PRAS goals. This will result in increased use of over water routings and will shift noise impacts from areas north and south of Logan Airport to areas east and west of it. However, these flight shifts will increase the number of Chelsea residents included in the 65 dB DNL noise contour. To mitigate these impacts, Massport and FAA will sound insulate the homes newly included in the project's 65 dB DNL contour. In addition, Massport and FAA will continue their residential sound insulation efforts for all residences within the 1998 65 dB DNL contour.

6.8.6 Other Environmental or Human Health Considerations

The Council on Environmental Quality (CEQ) asks federal agencies, to the extent practicable, to consider the following when assessing environmental justice impacts:

- Whether health effects [of the proposed action] are significant or above generally accepted norms;

- Whether the risk or rate of exposure to an environmental hazard [caused by the proposed action] is significant or appreciably exceeds the risk or rate of exposure to the general population;

- Whether health effects [of the proposed action] occur in minority or low-income populations [already] affected by cumulative or multiple adverse exposures from [other] environmental hazards;

- Whether [the proposed action] will cause significant impacts on the environment that adversely impact affected populations;

- Whether a significant, adverse impact on a minority or low-income population appreciably exceeds [similar] impacts on the general population; and whether the environmental effects occur in minority or low-income populations [already] affected by cumulative or multiple adverse exposures from [other] environmental hazards.

Environmental and health studies relating to the City of Chelsea have been reviewed in an effort to assess other cumulative or multiple adverse exposures within the affected minority population. Although demographic analysis has found no disproportionately high and adverse effect from direct project impacts, an analysis of these additional factors for the City of Chelsea was conducted since the area added to the 65 dB DNL contour under the Preferred Alternative includes this community. A summary of these studies follows.

Chelsea is a small (2.1 square mile) city with an ethnically diverse population. It is bounded on the north by the City of Everett, on the east by Mill Creek and the City of Revere, on the south by Chelsea Creek and East Boston, and on the west by the Mystic River and Charlestown. Access from Chelsea to East Boston is provided via the Chelsea Street and McArdle Bridges and to Charlestown and Downtown Boston via the Tobin Bridge, which carries Route 1 over the Mystic River. Designated truck routes through the City of Chelsea include Route 1, Beacham, Williams and Marginal Streets, Eastern Avenue, and parts of Broadway. Additional streets designated for truck traffic include Second and Spruce Streets and parts of Everett Avenue, as well as Gerrish Street and Crescent Avenue.

Approximately one-third of Chelsea's land area is commercial or industrial land that is either currently in industrial use or once housed heavy industries. Many of these sites are vacant or underutilized properties that border residential areas.[19] Much of the industrial property is concentrated on the waterfront along Marginal Street and Eastern Avenue. Chelsea is home to numerous oil and fuel storage facilities as well as industrial facilities that utilize toxic materials in their manufacturing processes. Given these characteristics, many of the environmental issues identified in Chelsea center on toxic discharges associated with industries in Chelsea and contamination of Chelsea Creek. Figure 6.8-3 illustrates Chelsea land use and environmental issues in relationship to the 29M Low Fleet scenario 65 dB DNL noise contours.

6.8.6.1 Industrial Pollution and Brownfields Initiatives in Chelsea

Industrial Pollution

The Massachusetts Department of Environmental Protection lists approximately 50 21E sites in Chelsea with some degree of oil or hazardous material contamination and approximately 115 spill incidents identified in accordance with the provisions of the Massachusetts Contingency Plan (310 CMR 40.000). (See Appendix I for a list of DEP sites.) There are no US Environmental Protection Agency Superfund sites in Chelsea, although the former Forbes Lithographic Company on Marginal Street is listed as a site awaiting a National Priority List (NPL) decision.

A survey by the Massachusetts Toxics Campaign Fund examined the extent of industrial pollution in Chelsea and its possible relation to the socioeconomic status of Chelsea residents.[20] The survey revealed that the most significant industrial pollution sources in Chelsea are found in the city's eastern sections in close proximity to residential neighborhoods, and in the sparsely populated western industrial section. The survey also recognized that higher levels of pollution appear to be present in neighborhoods with a higher percentage of low-income residents or minority populations. According to the survey, the census tract with the highest percentage of people of color living below the poverty line (census tract 1605) experienced the highest level of continuous toxic releases. In addition, the survey concludes that the two census tracts with the highest percentage of Hispanic residents (census tracts 1602 and 1604) demonstrated a higher incidence of toxic releases than other parts of the city.

The survey recommended that public access to information on industrial toxic hazards needs to improve, and that a closer examination of such hazards in close proximity to residential neighborhoods and schools be conducted. This survey did not compare industrial toxic release findings of Chelsea with other exposures in other communities.

Brownfield Initiatives

EPA has selected the 43 acre Everett Avenue Urban Renewal District in Chelsea as a Brownfields Assessment Demonstration Pilot. The objective of the project is to assess and plan for the clean up of the area in order to encourage redevelopment of the site. An EPA grant was also provided to STRIVE-Boston Employment Services, Inc. for a Brownfields Job Training Development Demonstration Pilot to train 60 low-income participants from Chelsea as environmental technicians.

▼

20 The Massachusetts Toxics Campaign Fund, *Industrial Pollution in Chelsea*, 1998.

6.8.6.2 Community Initiatives

There are numerous community groups active in environmental initiatives, including the Chelsea Human Services Collaborative / Green Space and Recreation Committee, and the Chelsea Creek Action Group, a coalition of the East Boston Ecumenical Community Council, Neighborhoods for Affordable Housing, and the Chelsea Human Services Collaborative / Green Space and Recreation Committee.

The Chelsea Human Services Collaborative was awarded an EPA Educational Grant in 1997 to provide educational outreach programs focused on environmental issues in Chelsea. This organization also received an EPA Environmental Justice Grant in 1998 to halt the expansion of and to address environmental and public health hazards associated with the 100,000-ton Eastern Minerals rock salt receiving, storage and distribution site located on Chelsea Creek. The Chelsea Human Services Collaborative also produced a series of maps that illustrate demographics, land use, industrial facilities, and pollution sources in Chelsea.

6.8.6.3 Other Environmental Documents

Environmental documents filed with the Massachusetts Environmental Policy Act (MEPA) Office relative to projects in Chelsea for the period from 1989 to the present (September 30, 1999) were also reviewed. Of those projects, only the following three resulted in the submission of an EIR:

- EOEA # 10335 - Massachusetts Water Resources Authority Combined Sewer Overflow
- EOEA# 9146 - Parking Garage, 270 Central Avenue
- EOEA# 8695 - Boston Harbor Dredging Project, Berthing Areas

The majority of the ENFs for Chelsea filed with MEPA were for new public buildings or infrastructure improvements. (See Table 6.8-11 for a list of other environmental documents filed with MEPA.)

6.8.6.4 Public Health

In addition to environmental effects, EO 12898 also directs federal agencies to consider adverse human health effects of its programs, policies and activities. CEQ guidelines direct agencies to consider relevant public health data to the extent that such information is reasonably available.

Table 6.8-11
Environmental Documents Filed with MEPA

EOEA No.	Project Name	Certificate Date	Location
11511	Everett Avenue Urban Revitalization	April 10, 1998	Everett Avenue, Chelsea
11476	Chelsea Police Station Renovation	March 13, 1998	19 Park Street, Chelsea
11068	Chelsea Parking Project	September 8, 1997	Eastern Avenue, Chelsea
10980	Chelsea Street Movable Bridge	January 9, 1997	Chelsea Street Bridge, Chelsea
10311	Chelsea Early Learning Center at the Shurtleff School	May 10, 1995	76 Congress Street, Chelsea
10100	Proposed Dredging in Chelsea River/ Eastern Minerals/ SMP Trust	January 13, 1995	37 Marginal Street, Chelsea
9981	Chelsea Middle School Project	June 23, 1994	170-180 Walnut Street, Chelsea
9810	Chelsea High School	March 10, 1994	Carter Street at Everett Avenue, Chelsea

8806	Revere Water Transmission Main Project	October 10, 1991	Chelsea: Hy-Sil Avenue, Reservoir Avenue, Carrol Way, Prospect Avenue, Broadway
8418	Maintenance Dredging at Three Marine Terminals	November 23, 1990	99 Marginal Street, Chelsea 22 Lee Burbank Highway, Revere - 900 First Street, South Boston
8329	Northeast Petroleum	August 10, 1990	324 Marginal Street, Chelsea

In response to EO 12898, public health issues in Chelsea were researched. Local[21] and state[22] public health agencies, as well as EPA Region 1 staff[23], [24] were interviewed, and it was determined that there are no published studies relative to public health issues in Chelsea. The Massachusetts General Hospital, Memorial Health Center in Chelsea is collecting information regarding asthma, but such information has not been published.[25] The only information available for Chelsea was a summary public health profile prepared by the Institute for Health Policy, Massachusetts General Hospital / Partners Healthcare System. This report indicated that in the period from 1989 to 1997, hospital discharges for asthma for Chelsea residents declined from a high of 433.1 per 100,000 population in 1992, to a low of 244.9 per 100,000 population in 1997. However, the 1997 rate of 244.9 for Chelsea residents was still higher than the Massachusetts average rate of

135.5 for the same year.[26] Additional public health information on the City of Boston and other communities was found to be available and is presented in Section 6.8.7 for informational purposes.

Interviews with local community groups indicate that there are public health concerns about emissions from private-sector petroleum facilities along Chelsea Creek (especially those located near the Tobin Bridge / Marginal Street waterfront), with the burning of high-sulfur fuels at Boston Edison's Mystic Plant in Everett, and with emissions from diesel trucks that drive through Chelsea neighborhoods.[27]

The Chelsea Creek Action Group was awarded an EPA grant in March 1999 to conduct a two-year study of environmental and health risks for East Boston and Chelsea residents living near Chelsea Creek. The purpose of the study was to conduct a comprehensive outreach effort to ascertain from residents, physicians, public health experts and environmental leaders what their perspectives are about environmental and health risks in the Chelsea Creek area in order to help the communities prioritize actions that can reduce those risks. A survey of residents in East Boston and Chelsea was conducted by the Chelsea Creek Action Group as part of Phase 1 of the comparative risk assessment to ascertain public opinion on issues regarding public health, the environment and quality of life. A total of 325 people were either interviewed or submitted surveys. A large number of people (124) did not respond to questions regarding their individual health or community health concerns (86). Air pollution was listed as the most frequent environmental concern (86 respondents), with cars, buses, airplanes and ships all mentioned as potential sources. Trash was listed second most frequently (65 respondents) as a concern. A little less than half of the residents responded to the information on quality of life issues and no particular quality of life issue was identified as more important than others.[28] Phase II of the study involves a resident community group further defining the major issues to address by incorporating the results of the survey and additional technical information provided by the EPA, state and city agencies. Phase II is anticipated to be completed by the end of 2001, with a final report and possible action plan by March 2002. [29]

Community health studies funded by Massport have addressed health issues relating to lead paint use in Chelsea. The studies have shown that elevated blood lead levels in children are associated with the presence of lead paint on or in residential units. Massport stopped using lead-based paint on the Tobin Bridge in 1977, and instead utilized an organic zinc-based paint as a substitute. Portions of the lead paint on the bridge were removed via grit blasting that utilized a vacuum system to remove and collect lead paint particles and grit so that they would not be released to the community. Massport financially supported a Chelsea community organization (CAPIC) that was

29 Telephone conversation with Susan Loucks, Chelsea Creek Action Group Project Coordinator, January 23, 2001.

conducting studies of elevated blood lead levels in children. Children and pregnant women living near the Tobin Bridge were tested, and those children with elevated blood lead levels were given medical treatment. In no cases were the blood lead levels a result of the painting process or lead flaking from the bridge. Rather the elevations were due to the presence of lead paint on or in residential units. Houses where lead paint was identified were eventually deleaded.

Massport also conducted an extensive soil removal program in areas near the bridge with elevated soil lead levels, regardless of the source of the contamination. Contaminated soils were replaced with clean soil and the area revegetated. Lead levels in the soil are monitored annually.

Currently, Massport utilizes an aluminized epoxy paint system that requires less removal of lead paint and employs power tool cleaning instead of grit blasting. All painting operations are carefully monitored for particulate emissions as well as air lead levels.

6.8.7 Other Public Health Studies

The available public health studies for communities adjacent to Logan Airport were reviewed, consistent with the directives of CEQ Guidance. Public health status reports prepared by the Boston Department of Health and Hospitals and the Boston Public Commission were available for the City of Boston. Comparable public health reports were not available from the Public Health Departments of Chelsea,[30] Revere,[31] and Winthrop.[32] The available studies are summarized below for informational purposes.

Boston Neighborhood Health Status Report, Boston Department of Health and Hospitals (1994)

This series of reports identifies and discusses health-related issues for each of Boston's sixteen neighborhoods. These reports compare reportable data relative to births (natality), deaths (mortality) and illness (morbidity) to the demographics/ socio-economics of each of the neighborhoods and to the City of Boston as a whole. They are intended to provide a broad picture of the health of the community, as opposed to a study correlating human health to other environmental factors. For example, no correlation between air pollution and public health was made. Health status indicators were also compared to federal U.S. Department of Health and Human Services goals set forth in *"Healthy People 2000: National Health Promotion and Disease Prevention Objectives."* A summary of key findings for the neighborhoods closest to the airport, East Boston and South Boston, are presented below:

30 Telephone Conversation - Frank Singleton, Chelsea Public Health Department, 9/10/99.
31 Telephone Conversation - Francis Hyland, Revere Public Health Department, 9/10/99 /Telephone conversation with Nicolas Catinazzo, Revere Public Health Department, 1/19/01.
32 Telephone Conversation -Bea Farnham, Winthrop Public Health Department, 9/14/99/ Telephone conversation with Bea Farnham, Winthrop Public Health Department,1/23/01.

- **East Boston—**East Boston contained approximately 5.7 percent of the City of Boston's residents in 1990. The top five leading causes of death in East Boston were: heart disease, cancers, accidents, pneumonia / influenza and liver disease. The age adjusted rate (AAR) of cancer deaths per 100,000 in East Boston was 134.5, which is close to the Healthy People 2000 goal of 130 deaths per 100,000 population. East Boston has a lower rate of cancer deaths than Boston as a whole, which has an AAR for cancer deaths of 157.0. The overall standard mortality ratio for the East Boston population was 0.86, indicating that fewer deaths occurred in East Boston than expected when compared to the mortality in Boston as a whole.

- **South Boston**—South Boston contained approximately 5.1 percent of the City of Boston's residents in 1990. The top five leading causes of death in South Boston were: heart disease, both cerebrovascular disease (strokes) and accidents, chronic obstructive pulmonary disease and pneumonia / influenza. The age adjusted rate (AAR) of cancer deaths per 100,000 in South Boston was 198.3, which is higher than the AAR for cancer deaths of 157.0 in Boston, and the Healthy People 2000 goal of 130 deaths per 100,000 population. The standard mortality ratio for the South Boston population was 1.32 indicating that 32 percent more deaths occurred in South Boston than expected when compared to the mortality in Boston as a whole.

Report to the Mayor, Health of Boston (1999, 2000)

The *Health of Boston* is an annual public health assessment to provide the local government and general public with an overview of health issues and problems that affect the Boston population. The information in this report is used by the Boston Public Health Commission to assist in the establishment of public health priorities for the present and future. The report is organized by health care subject, such as lung cancer, breast cancer, suicide, infant mortality, HIV / AIDS, cigarette smoking, health insurance and adolescent pregnancy. This report does not present health issues in relation to specific environmental conditions.

The *Health of Boston 1999* reported that the leading cause of death in the city was cancer, followed by heart disease, injury, cerebrovascular disease (stroke) and homicide. Even though it was the top cause of death, cancer-related mortality decreased by 4.7 percent between 1991-1994 and 1995-1997. The age-adjusted lung cancer mortality rate in Boston decreased by 10.9 percent for the same period.

Cancer, heart disease and injury remained the top three causes of death, but HIV / AIDS and substance abuse were reported as the fourth and fifth leading causes of death in the *Health of Boston 2000.* Cancer–related mortality continued to decline, with a 5.2% decrease in between the periods of 1993-1995 and 1996-1998. The lung cancer age-adjusted mortality rate of 41.7 deaths per 100,000 population is 6.9 percent below the Healthy People 2010 target rate goal of no more than 44.8 deaths per 100,000.

The 1999 report presented the status of environmental health issues in Boston, specifically childhood lead poisoning and asthma. Asthma is a chronic inflammatory lung disease characterized by recurrent and reversible symptoms of airflow obstruction. House dust mites, cockroaches, mold, and animal dander have been identified as the principal allergens that trigger asthma symptoms. Secondhand smoke, upper respiratory viral infections, and certain air pollutants can also trigger an attack and worsen the effects of allergens. Asthma is the ninth leading cause of hospitalizations in the United States. Approximately 6.5 percent of the population in Massachusetts were estimated to have asthma in 1998. Boston residents had an average annual rate of asthma hospitalizations (3.5 per 1000 residents) that was double the rate for all Massachusetts residents, with children having the highest rates. The two neighborhoods with the highest rates of asthma in 1997 based on administration of the drug albuterol by Emergency Medical Technicians were Dorchester (30.5 percent) and Roxbury (21.0 percent), followed by Jamaica Plain (9.4 percent) and Mattapan (9.0 percent). East Boston and South Boston each accounted for 4.3 percent of the albuterol incidents.

The 2000 report indicated that over time, asthma hospitalization among children has declined in Boston, despite an increase in the overall incidence of childhood asthma. The number of Boston residents under 18 that were hospitalized for this condition in 1998 fell 11.0% in one year, from 636 in 1997 to 566 in 1998. Children under five had the highest rates of asthma hospitalization, with males more likely than females to be hospitalized for asthma. Roxbury, South Dorchester and North Dorchester had the city's highest rate of asthma hospitalization for males under five years of age for the period of 1994 to1998, with a rate per 1,000 population of 18.6, 14.8 and 13.7, respectively. By comparison, the rate of asthma hospitalization for males under five years of age for the same period for East Boston was 9.5, and the rate for South Boston was 8.2. Roxbury, Jamaica Plain, North Dorchester, and the Fenway had Boston's highest rates of asthma hospitalization for females under five years of age, but these rates were lower than for males of the same age.

South Boston Particle Source Apportionment Study by the Harvard School of Public Health

This ongoing study is attempting to characterize air quality within the South Boston community by measuring particulate matter and gaseous pollutants. The purpose of the study is to identify and assess the contribution of various air pollution sources through air monitoring and modeling, provide data for the purposes of health effects assessment, and to recommend measures to improve air quality within the community in a cost-effective manner.

An air pollution monitoring study was conducted during the period of January 1995 through March 1997 that measured particulate matter 10 micrograms or less in diameter (PM_{10}), and particulate matter 2.5 micrograms or less in diameter ($PM_{2.5}$). Initial results of the study indicate that the majority of fine particles ($PM_{2.5}$) observed at the Boston monitoring sites are associated mostly with sources located outside of the Boston metropolitan area, and to a lesser extent with local motor vehicle emissions. Particulate and gaseous air pollutant concentrations observed during the study were typical of the

northeastern United States. In addition, the two-year average particulate concentration levels experienced in South Boston were lower than those experienced in other Northeastern urban environments, such as Washington, DC, Philadelphia, PA, and Nashville, TN. The highest average fine particle concentrations in South Boston were found at the monitoring site adjacent to the Southeast Expressway (I-93). [33]

Winthrop Community Health Survey

The July 1999 survey by the Winthrop Environmental Health Facts Subcommittee, a voluntary group made up of residents of the Town of Winthrop, studied whether activities at Logan Airport have a negative impact on their health. The survey indicated that individuals residing in Winthrop neighborhoods surrounding Logan Airport show a considerably higher incidence of respiratory and cardiovascular diseases, including lung cancer, chronic obstructive pulmonary disease, asthma and allergic rhinitis, compared to the statewide average. The survey acknowledged that it has not been possible to determine whether Logan Airport operations contribute to this health burden, since the urban location of these communities presents a complex picture of pollution sources.

The methodology utilized in the survey included dividing the town into ten neighborhoods. Two neighborhoods were selected as likely representing areas of highest and lowest exposure. A questionnaire was devised and interviews conducted on diagnosed illnesses, symptoms, frequency and smoking history. The survey stated that individuals in the presumed high exposure zones experienced approximately twice the frequency of symptoms when compared with the presumed low exposure group. The survey also recognized that the true difference in exposure to airborne pollutants between the low and high exposure groups is not known, the total sample size is small, and that it cannot claim to have proven an association between airport-related pollution generation and respiratory disease in Winthrop.

The Massachusetts Department of Public Health, Bureau of Environmental Health Assessment reviewed the results of the Winthrop Health Study and concluded that while the study raised interesting questions, the methodology used to conduct the study and interpret the results limited the validity of the conclusions which were drawn by the investigators.[34]

Massachusetts Department of Public Health/Bureau of Environmental Health Assessment Public Health Study

Language in the 1999 state budget states that "$150,000 shall be expended for the purpose of the Director of Environmental Health Assessment to conduct an environmental assessment of the health impacts of Logan Airport on any community that is located within a five-mile radius of the airport and is potentially affected by said airport."

▼

33 Harvard School of Public Health, *Report on Initial Findings from the South Boston Air Quality Monitoring Study*, March 26, 1999.

34 Letter from Susan K. Condon, Director, Bureau of Environmental Health Assessment to William P. Frazier, Director, Department of Health, Town of Winthrop dated January 5, 2000.

The Massachusetts Department of Public Health / Bureau of Environmental Health Assessment (BEHA) proposes to study the relationship between air pollution and public health, focussing on respiratory and cardiovascular effects for communities within a five-mile radius of Logan Airport. BEHA will examine human exposures to jet fuel emissions, particulate matter and meteorological factors, as well as behavioral (e.g. cigarette smoking), occupational, and construction-related exposures. Other potential area sources such as rental car and vehicle service and maintenance facilities will also be examined. A series of meetings with communities within the study area as well as with Massport were held during the summer of 2000 to discuss the scope and methodology for the study. The final protocol for the study is being developed and the study is expected to be completed in the summer of 2002.

Massport's Participation in Air Quality/Public Health Studies

Massport has been cooperating with the City of Boston and the Commonwealth of Massachusetts on public health issues. In September 1995, the Secretary of the Executive Office of Environmental Affairs (EOEA) established a Scope for the analysis of potential environmental impacts of airport-related air emissions. In response to EOEA's directive, Massport consulted with both the Massachusetts Department of Public Health and the Boston Department of Health and Hospitals. Discussions focused on addressing general community concerns and determining the nature and extent of follow-up required to identify potential sources of air emissions.

In January 1996, Massport reviewed available public health data, including mortality and morbidity data from each neighborhood report and cancer incidence data available from the Massachusetts Department of Public Health. These data indicated that causal relationships cannot be determined at this time, a conclusion which was confirmed by state and local agencies with public health expertise.

Massport has provided public health agencies with off-airport air quality monitoring data, results from monitoring conducted by the Massachusetts Department of Environmental Protection (DEP) adjacent to the Sumner Tunnel entrance, and emissions inventories compiled for the Logan Airport GEIRs and Annual Updates.

Massport prepared the Soot Deposition Study[35] and shared the findings with the Boston Public Health Commission and the state Department of Public Health. That study indicated that there were no ongoing, chronic soot impacts from airport-related activities and that soot deposition in communities adjacent to Logan Airport resulted primarily from ambient urban conditions, as opposed to aircraft sources at the airport.

35 *Soot Deposition Study: Logan Airport and Surrounding Communities*, prepared for Massport, prepared by: KM Chng Environment, Inc. January 1997.

Since the completion of the *Boston-Logan International Airport 1994/1995 Generic Environmental Impact Report*, Massport has continued discussions with public health agencies, and attended meetings and reviewed results from the *South Boston Particle Source Apportionment Study*, sponsored by the Harvard School of Public Health (HSPH). Massport is also cooperating with the Massachusetts Department of Public Health / Bureau of Environmental Health Assessment in the development of the protocol for the Logan Airport public health study. Massport will continue to facilitate monitoring of airport-related emissions by HSPH and DEP by assisting in monitoring site selection and providing agencies with air quality data, airport activity data and meteorological data.

6.8.8 Mitigation and Off-Setting Benefits

In making a determination regarding disproportionately high and adverse effects on minority and low-income populations, the Final US DOT Order directs FAA to take into account mitigation and enhancement measures as well as all off-setting benefits to the affected minority and low-income populations.

Mitigation

Noise has been identified as the only impact to surrounding communities associated with implementation of the Preferred Alternative. While the noise impact in Chelsea falls below the FAA threshold for identifying significant adverse impacts, Massport and the FAA recognize the high representation of low-income and minority populations within Chelsea, and the presence of pre-existing environmental conditions within the community that are unrelated to Logan. In recognition of these factors, Massport and the FAA are committing to providing sound insulation to all Chelsea residents newly included in the project's 65 dB DNL contour.

Noise impacts will be mitigated by sound insulating affected residences in Chelsea that fall within the 65 dB DNL contour for the Preferred Alternative as defined by the 29M Low Fleet scenario. To the extent that federal funding is provided, the proposed sound insulation program will include not only all residences that fall within the Preferred Alternative 's 65 dB DNL contour when compared to the Airside No Action 65 dB DNL contour, but also those that fall within the actual 1998 65 dB DNL contour as presented in the *Logan Airport 1998 Annual Update*. The number of dwelling units in Chelsea to be sound insulated is estimated to be 1,100 to 1,200 dwelling units. For the eligible residences, the FAA will fund building code upgrades, to the extent necessary to implement sound insulation. The number of residences to be included within the noise mitigation program is subject to a more detailed block by block analysis to be performed during implementation.

Off-Setting Benefits

The benefits associated with Logan Airport are provided without regard to race, creed, color, or economic status, and include the transportation services provided to passengers flying in and out of Logan, as well as jobs and economic benefits to Boston and other communities adjacent to the airport.

Logan Airport is a significant contributor to the economy and a major employer for the metropolitan region. According to a 1995 survey, approximately 14,551 persons were employed at the airport.[36] Of those employed at Logan, the largest percentage (18.5 percent, or 2698) live in the City of Boston, with most (1230) living in East Boston. Other communities with significant employment at Logan Airport include Revere (1225), Winthrop (884), Lynn (476), Peabody (357), Malden (354), Saugus (346), Chelsea (294), Everett (283), and Salem (210). These ten communities account for 49 percent of the employment at Logan.

Logan Airport is an essential component of the economic health of both the Metropolitan Boston area and the New England region. The regional economy is largely comprised of a mix of travel-intensive service industries, including high-technology, financial services, and tourism, that depend upon high-quality air transportation services. It is estimated that the annual contribution of Logan Airport to the economy is $5 billion of direct and indirect local spending.[37]

As part of the Logan Airside Improvement Project, Massport is taking initiatives to promote Chelsea's greater participation in the economic benefits of Logan. Currently, approximately 294 residents of Chelsea are employed at Logan. In an effort to increase the level of airport employment of Chelsea residents, Massport will encourage airport-based employers to recruit employees from, and conduct job training initiatives targeted at airport affected communities including Chelsea. Massport also proposes to work with the Chelsea Chamber of Commerce to establish business connections with Chelsea businesses.

Massport is also facilitating increased airport employment opportunities and other economic initiatives for Chelsea. Currently, Massport provides to Chelsea $500,000 in annual in-lieu-of-tax payments; $500,000 in economic development grants; and approximately $70,000 in annual grants for student summer employment programs, scholarships, athletic, elderly and educational programs. In addition the $300,000 Chelsea Gateway Beautification Project that will landscape the entrances to the City of Chelsea from the Tobin Bridge is expected to begin construction in the spring of 2001.

36 1995 Logan Employment Survey, Massachusetts Port Authority.
37 Fiscal 1998 Logan Economic Impact Study, Massachusetts Port Authority.

6.8.9 Public Participation Process

6.8.9.1 Public Participation Directives

Under NEPA and the federal Environmental Justice policy, agencies should work to ensure that public documents, notices, and other information relating to impacts of the proposed action on human health and the environment are concise, understandable, and readily available to the public, including minority and low-income populations. Public participation should occur early in the NEPA process and should continue through scoping, draft, and final EIS phases. Environmental justice review should heighten attention to Alternatives, mitigation strategies, monitoring needs and preferences expressed by the affected community or population. Pursuant to the Final US DOT Order, meaningful opportunities for public involvement by members of minority populations and low-income populations are to be provided during the planning and development of activities. Additionally, access to public information concerning the human health and environmental impacts of activities, including information that will address the concerns of minority and low-income populations, is to be provided.

6.8.9.2 Public Participation for the Airside Improvement Project

Since the initial scoping[38] of the proposed Logan Airside Improvement Project, and throughout each phase of the environmental review process, FAA and Massport have established a dialogue with community leaders and the public through public hearings, briefings, responses to comment letters, and circulation of the Airside Project Draft EIS/EIR for public review and comment.[39] Over 700 copies of the Airside Project Draft EIS/EIR were distributed for public review including copies sent to the Chelsea Human Services Collaborative, the Centro Hispano de Chelsea, and the Chelsea Commission on Hispanic Affairs. Copies of the Airside Project Draft EIS/EIR were also distributed to every public library in each of the 28 communities represented on the CAC. Approximately 1,300 comment letters were received on the Airside Project Draft EIS/EIR.

Over 100 meetings, designed to elicit participation from community leaders and the public at large, have taken place since the project scoping. To encourage participation Massport conducted meetings in more than 15 communities surrounding Boston and Logan, including Chelsea, Winthrop, East Boston, South Boston, Charlestown, Revere, Jamaica Plain, Milton, Dorchester and Roxbury.

▼

38 Massport, Proposed Scope: Airside Project Draft EIS/EIR Logan Airside Improvement Planning Project" (The initial stage of this evaluation is a planning effort that is designed to use the operations and environmental analysis, and related public input process to further assess the efficacy and interrelationship of the various improvement concepts.) (1995).

39 66 comment letters were received in response to the Environmental Notification Form (ENF). *See* Commonwealth of Massachusetts Executive Office of Environmental Affairs, Certificate of the Secretary of Environmental Affairs on the Environmental Notification Form for Logan Airside Project improvements Planning Project EOEA #10458 (Nov. 22, 1995). Response to comments on the ENF were provided in Volume II of the Logan Airside Project improvements Planning Project, Airside Project Draft EIS/EIR.

The Airside Review Committee (ARC) was formed in December 1995, to provide advisory input from the community to Massport and the FAA. The ARC consists of the Logan Airport Citizens Advisory Committee (CAC) to Massport and representatives of regional business and aviation organizations. The CAC is comprised of representatives from 28 neighborhoods, cities and towns. The ARC has met 15 times since it was formed, providing an exchange of ideas and concerns at every stage of the project development process, and there have been approximately 15 additional meetings with the CAC that Massport staff have attended. Extensive information about the proposed action and its environmental impacts was presented to the ARC by agency staff and consultants, and ARC members commented, questioned, and discussed their concerns with technical presenters and Massport planning staff.

Presentations to the public were provided in various formats, from briefings to large public meetings. For example, Massport provided a briefing to Chelsea community leaders on January 19, 1999. There were approximately 35 people in attendance, including members of the Chelsea City Council, and representatives of community groups. At the March 3, 1999 Chelsea City Council public hearing, over one hundred citizens had the opportunity to speak and comment to Massport officials following a presentation of the proposed project; the meeting was broadcast on the local cable station. Consistent with FAA policy of providing translation on request, a Spanish-language interpreter was present at the February 23, 1999 meeting with the Latin American Planning and Development Group**,** at which representatives of the Chelsea Hispanic Community were present.

At public meetings and at the request of interested community members, Massport has provided full access to the public concerning the Logan Airside Improvements Planning Project and its associated social and environmental effects. At meetings, Massport and FAA officials have provided an overview of Logan Airport's current operations and the need for changes. In addition, they have described the impacts of proposed changes on particular communities and efforts to mitigate adverse noise impacts. Public participation has resulted in additional studies and refinement of the mitigation program. (See Chapter 8 for a discussion of mitigation.)

6.8.10 Summary of Findings

The Preferred Alternative is intended to reduce congestion and delay at Logan, and to increase the safety and efficiency of airport operations.

A disproportionately high and adverse effect means an adverse effect that is predominately borne by a protected population, or an adverse effect which is appreciably more severe or greater in magnitude in its impact on a protected population than on other populations which are also affected. The Final US DOT Order directs FAA to determine whether its programs, policies, and activities will have a disproportionately high and adverse impact on minority or low-income communities, taking account of mitigation, enhancement measures, and all off-setting benefits to the affected populations, as well as the design,

comparative impacts, and the relevant number of similar existing system elements in non-minority and non-low-income areas.

There is no disproportionate adverse impact associated with the Preferred Alternative. The increased exposure to aircraft noise is 0.6 dB or less in affected communities, which is below the FAA threshold for determining significant adverse impacts. Mitigation of the increased noise will be provided in the form of sound insulation.

In addition, off-setting economic benefits will be provided to Chelsea to help that community participate more fully in the economic benefits of Logan.

Taking account of the small incremental noise impacts within the affected areas, the proposed sound insulation and economic initiatives, the economic benefits of Logan Airport in which Chelsea residents will share, and the safety, operational, and environmental benefits of the Preferred Alternative to the population at large that are not achievable under other Alternatives, the Preferred Alternative will not have a disproportionate high and adverse impact on minority or low-income communities.

6.9 Construction Impacts

This section provides an overview and description of the proposed airside improvement construction activities and associated impacts. Construction activities associated with the Preferred Alternative include Runway 14/32 and the Centerfield Taxiway, as well as taxiway realignments and extensions associated with Taxiway Delta, Taxiway November and the configuration of the Southwest Corner. All construction phases and sequences would be carefully planned to ensure the continued safe and efficient operation of the airport, and the successful and timely completion of the project.

Potential impacts resulting from the construction of the Airside Project improvements Planning Project can be separated into two broad categories for discussion purposes: impacts on the direct users of the airfield, and impacts on the group consisting of the surrounding communities and other users of the airport in general. It is Massport's goal to avoid or to mitigate such impacts to the maximum extent possible.

The estimate of truck volumes presented in this Supplemental DEIS/FEIR is less than that presented in the Airside Project Draft EIS/EIR, which had assumed a worst case scenario. Since publication of the Airside Project Draft EIS/EIR, a subsurface investigation (boring) program was undertaken to characterize the suitability of the soils for construction of the Airside Project improvements. This investigation found that much of the existing soil material on the airport is suitable for construction, and thus the total estimate of soil to be excavated and removed from the airfield has been reduced. (See Section 6.7 for a more detailed discussion of soil characteristics.) This in turn reduces the amount of truck trips required for construction. In addition, the Airside Project Draft EIS/EIR had assumed that 215,000 cubic yards of soil stockpiled by the Massachusetts Highway Department Central

Artery Project (CA/T) on Governors Island would need to be relocated to construct Runway 14/32. However, this has been moved off-site for use as cover material to close the Rubchinuk Landfill in Middleton, Massachusetts. (See Section 5.7.2 for additional discussion.) Transfer of the approximately 240,000 cubic yards of the CA/T soil from Governor's Island was completed in November 2000. See Table 6.9-1 for excavate material quantities from Logan Airside Project improvements.

Table 6.9-1
Excavated Material From Construction of Logan Airside Project improvements

	Total Excavated Material * (cubic yards)	Unclassified Excavate Reused On Site (cubic yards)	Unclassified Excavate Removed from Site (cubic yards)	Existing Bituminous Pavement Removed from Site (cubic yards)
Runway 14/32	111,000	37,000	45,000	29,000
Centerfield Taxiway	52,000	41,000	11,000	0
Southwest Corner Taxiway	14,000	5,000	0	9,000
Taxiway November	55,000	500	43,000	11,500
Taxiway Delta	32,000	0	32,000	0
TOTAL	264,000	83,500	131,000	49,500

Source: HNTB 12/1/99
Includes soil and existing bituminous pavement.

6.9.1 Construction Elements of the Preferred Alternative

This section describes the individual construction elements of the Preferred Alternative. A summary of construction costs and duration of the Preferred Alternative, by individual construction elements, is presented in Table 6.9-2.

Table 6.9-2
Summary of the Preferred Alternative by Construction Elements

Construction Element	Construction Cost Estimate ($ millions)	Estimated Construction Period (Days[1])
Unidirectional Runway 14/32	33	300
Centerfield Taxiway	20	See Note 2
Southwest Taxiway System Reconfiguration	14	240
Taxiway Delta Extension	6	180
November Taxiway Realignment	3	180
TOTAL	$76	Phased over ± 5 years

1 Days are consecutive calendar days, inclusive of Saturdays and Sundays. Does not include winter construction shut down period.
2 Construction of the northern segment of the Centerfield Taxiway is estimated to take 180 days; construction of the southern segment of the Centerfield Taxiway is estimated to take 210 days. There is some overlap of the two construction periods.

6.9.1.1 Unidirectional Runway 14/32

This element involves the construction of a new 5,000-foot runway and associated taxiway. The runway would be 100 feet wide with two 35-foot wide paved shoulders. The project would also include reconstruction of 2,000 feet of existing pavement in the South Cargo Area for use as a taxiway to the Runway 14 end.

Construction of Runway 14/32 would require the removal of existing surface vegetation and approximately 29,000 cubic yards of pavement and 45,000 cubic yards of unclassified excavated soil material, which will be taken off-site for reuse/recycling. The subsurface investigation conducted in the area of the Airside Project improvements found that the soils in the vicinity of proposed Runway 14/32 are well drained and provide a suitable foundation for construction. Therefore, less soil material needs to be removed from the site than had been assumed in the Airside Project Draft EIS/EIR. A subbase and crushed aggregate base course will be placed prior to paving with a bituminous concrete mix. All aggregate base would be obtained from commercial sites rather than disturbed sites. Should Massport need to find new sites for aggregate base or sand materials, Massport will do so from sites that have undergone the appropriate environmental review and permitting processes. A runway/taxiway drainage system would be constructed and integrated into the existing airfield drainage system, and conduits for lighting and other instrumentation would be installed.

Construction of Runway 14/32 would require demolition of Buildings 60 and 61 in the South Cargo area, which together have a total footprint of 155,000 square feet. Both buildings are essentially large hangar-type spaces with truck loading docks located along the landside and large roll-up doors located along the airside for passage of freight and cargo. Ground floor slabs and exterior foundation walls are poured concrete. Exterior walls are primarily metal panels over steel framing, with some masonry construction between the loading dock roll-up doors at the landside. Flat roofs are supported by steel columns, girders and trusses. Demolition of these buildings would yield approximately 35,000 cubic yards of construction debris. Table 6.9-3 provides a breakdown of construction debris by type of material. All demolition material will be recycled to the extent feasible.

Table 6.9-3
Total Estimated Building Demolition Materials

Material	Volume (cubic yards)
Subsoil	6,400
Concrete	9,400
Masonry	9,100
Metal	4,000
Miscellaneous Building Materials	5,700
Total	34,600

6.9.1.2 Centerfield Taxiway

The Centerfield Taxiway would be constructed between, and parallel to, Runways 4L/22R and 4R/22L. The taxiway would be 9,300 feet long (a length that incorporates some elements of the southwest taxiway system) and 100 feet wide, with two paved shoulders each 35 feet wide. A parallel service road, 24 feet wide, would be constructed along the eastern side of the Centerfield Taxiway.

Construction of the Centerfield Taxiway would entail the removal of existing vegetated soil. Approximately 11,000 cubic yards of existing soil will be excavated and removed from the site and replaced with coarser and better draining materials to form a suitable base. Approximately 41,000 cubic yards of unclassified excavate will be reused on site. The taxiway drainage system would be constructed and integrated into the existing airfield drainage system, and conduits for lighting and other taxiway instrumentation would be installed.

Construction of the Centerfield Taxiway would take place in two segments: Centerfield Taxiway-North, situated between Taxiway Romeo and Runway 15R/33L, and Centerfield Taxiway-South, between Runway 15R/33L and Taxiway Whiskey.

6.9.1.3 Southwest Corner Taxiway System Reconfiguration

Optimization of the present southwest corner taxiway system would entail the realignment of Taxiways Alpha, Echo, Kilo, Sierra and Whiskey, and integration of the Centerfield Taxiway. Approximately 9,000 cubic yards of existing bituminous pavement would be excavated and removed from the site. No existing soil would be removed from the site for construction of these improvements. Approximately 5,000 cubic yards of unclassified excavate will be reused on site.

Construction would consist of restriping existing pavement and the placement of new pavement and drainage in other areas. As noted in Section 6.5.1, approximately 6.1 acres of new vegetated area would be created upon completion of the taxiway optimization.

6.9.1.4 Taxiway Delta Extension

Taxiway Delta would be extended approximately 1,800 feet from the intersection with Taxiway Charlie southwest to Runway 4R/22L. Associated with this extension would be a slight realignment of the east end of Taxiway Echo to meet Taxiway Delta. Taxiway Delta would be 100 feet wide with two 35 foot paved shoulders. It is estimated that 32,000 cubic yards of soil material would be excavated and removed from the site during construction.

6.9.1.5 Taxiway November Realignment

The realignment of Taxiway November would consist of the reconstruction of approximately 1,800 linear feet of pavement, resulting in a taxiway 100 feet wide with two 35-foot wide paved shoulders. A majority of the area to be reconstructed is within the footprint of the existing taxiway, and construction would result in the excavation and

removal of approximately 43,000 cubic yards of fill and 11,500 cubic yards of existing bituminous pavement. Approximately 500 cubic yards of material will be reused on site.

6.9.2 Construction Sequence

A multi-year phased construction sequencing program has been designed to implement the construction elements of the Airside Project. The following policies guide the logic of the sequence:

1. Aircraft operational and safety needs take precedence over construction activity. Airport activity, runway configurations and so on dictate construction sequence, phasing and pace - not vice versa. Particularly where construction entails tying into an existing runway or taxiway, Massport Operations personnel would strictly control construction activity, in close coordination with FAA air traffic control personnel.
2. Construction of Runway 14/32 would occur first. This runway would significantly decrease congestion and delay at Logan, and would provide increased flexibility to FAA control tower personnel and Massport in devising taxiway routings during reconfiguration of the Southwest Taxiway System.
3. The Centerfield Taxiway would be built after Runway 14/32. This would permit Massport to address taxiway congestion and delay at Logan, thus eliminating some elements of noise and air quality emissions. Once in place, the Centerfield Taxiway would permit new taxi patterns bypassing the Southwest Corner to be established, thus isolating it and enabling construction activity to proceed in this location.
4. Taxiway improvements would then be addressed in an order which further promotes airfield safety and efficiency.

The work would be phased over five years, beginning in Year 1 with construction of Runway 14/32. A year-by-year summary of construction activity is illustrated in Table 6.9-4.

6.9.2.1 Construction Activities

A series of different construction contracts would be issued for each of the construction elements to be accomplished. The contractor(s) would be required to work an accelerated schedule during the first, second and third years in order to complete all of the proposed work. This would require the contractor to work extended periods of time (six or seven days a week, 12 to 16 hours a day) or the weekends at critical points in time. Construction work will occur primarily during the period of April through December with the exception of demolition work in the South Cargo area, which could occur during the months of January, February, and March if the weather permits.

Table 6.9-4
Construction Sequence and Schedule

Construction Element	Year 1 2003 Quarter 1	2	3	4	Year 2 2004 Quarter 1	2	3	4	Year 3 2005 Quarter 1	2	3	4	Year 4 2006 Quarter 1	2	3	4	Year 5 2007 Quarter 1	2	3	4
Runway 14/32	■	■	■	■																
Centerfield Taxiway						■	■	■												
Southwest Taxiway										■	■	■								
System Reconfiguration																				
Taxiway Delta Extension														■	■					
Taxiway November Realignment																		■	■	

The general nature of the construction activity is similar to that of a highway construction or rehabilitation project: excavation; placement and compaction of fill; installation of electrical conduits, drainage pipes and appurtenances; placement of asphalt; and installation of airport lighting and navigation systems.

Figure 6.9-1 illustrates the year-by-year location of construction activities.

Year 1

- Construction Element..... Runway 14/32
- Work Periods ..... January 2003 - December 2003

Following the receipt of all environmental and procedural clearances, construction of Runway 14/32 will begin with the following preliminary items: relocation of the Runway 27 localizer (a navigation aid) and realignment of Taxiway Bravo; relocation of the tenants and operations in Building 60, and the subsequent demolition of Building 60 and 61.

Runway 14/32 is intended to be operational for visual flight rules (VFR) operations in late 2003 or early 2004, after FAA flight checks.

Most construction work for Runway 14/32 would occur during daylight hours. However, at critical locations, such as the realignment of Taxiway Bravo the intersection with Runway 4R, construction will take place at night and/or weekends during periods of decreased airfield activity.

Year 2

- Construction Element.....Centerfield Taxiway
- Work Periods .....April 2004 - December 2004

Construction of the Centerfield Taxiway will include excavation and placement of subgrade material, paving, drainage, electrical work and tie-ins to the existing taxiway systems as well as final grading, loam and seeding.

During the construction of the Centerfield Taxiway, the contractor's forces will have to obtain ATC tower clearance to cross active taxiways and runways.

Year 3

- Construction Element.....Southwest Taxiway System Reconfiguration
- Work Periods .....April 2005 - December 2005

Nighttime and weekend construction will be necessary for the reconfiguration of the Southwest Taxiway System, due to the operational sensitivity of these taxiways. Small sections of the overall project will be phased to minimize operational impacts to the airport. For construction to proceed, requests will be made to Massport Operations and FAA ATC personnel to pavement these sections to aircraft traffic on a nightly basis (11:00 PM to 6:00 AM) or during "weekend specials" (11:00 PM Friday to 2:00 PM Sunday). Construction will take place within these limited periods.

Year 4

- Construction Items.....Taxiway Delta Extension
- Work Periods .....April 2006 - September 2006

A major portion of the Taxiway Delta extension will be constructed during the daytime period. Given the proximity of multiple runways and the required crossing of these runways by contractor vehicles and equipment, construction activity in this area is particularly sensitive. Tie-ins of Taxiway Delta to the existing runways and other taxiways will require nighttime or weekend construction to minimize operational impacts.

Year 5

- Construction Element.....November Taxiway Realignment
- Work Periods .....April 2007 to September 2007

As construction here would impact operations on Runways 15R and 15L, as well as ground movements of aircraft taxiing to/from Runways 22R and 22L, the bulk of construction activity will take place at night and weekends. Operational impacts to taxiing aircraft will be mitigated by assigning this traffic to the Centerfield Taxiway.

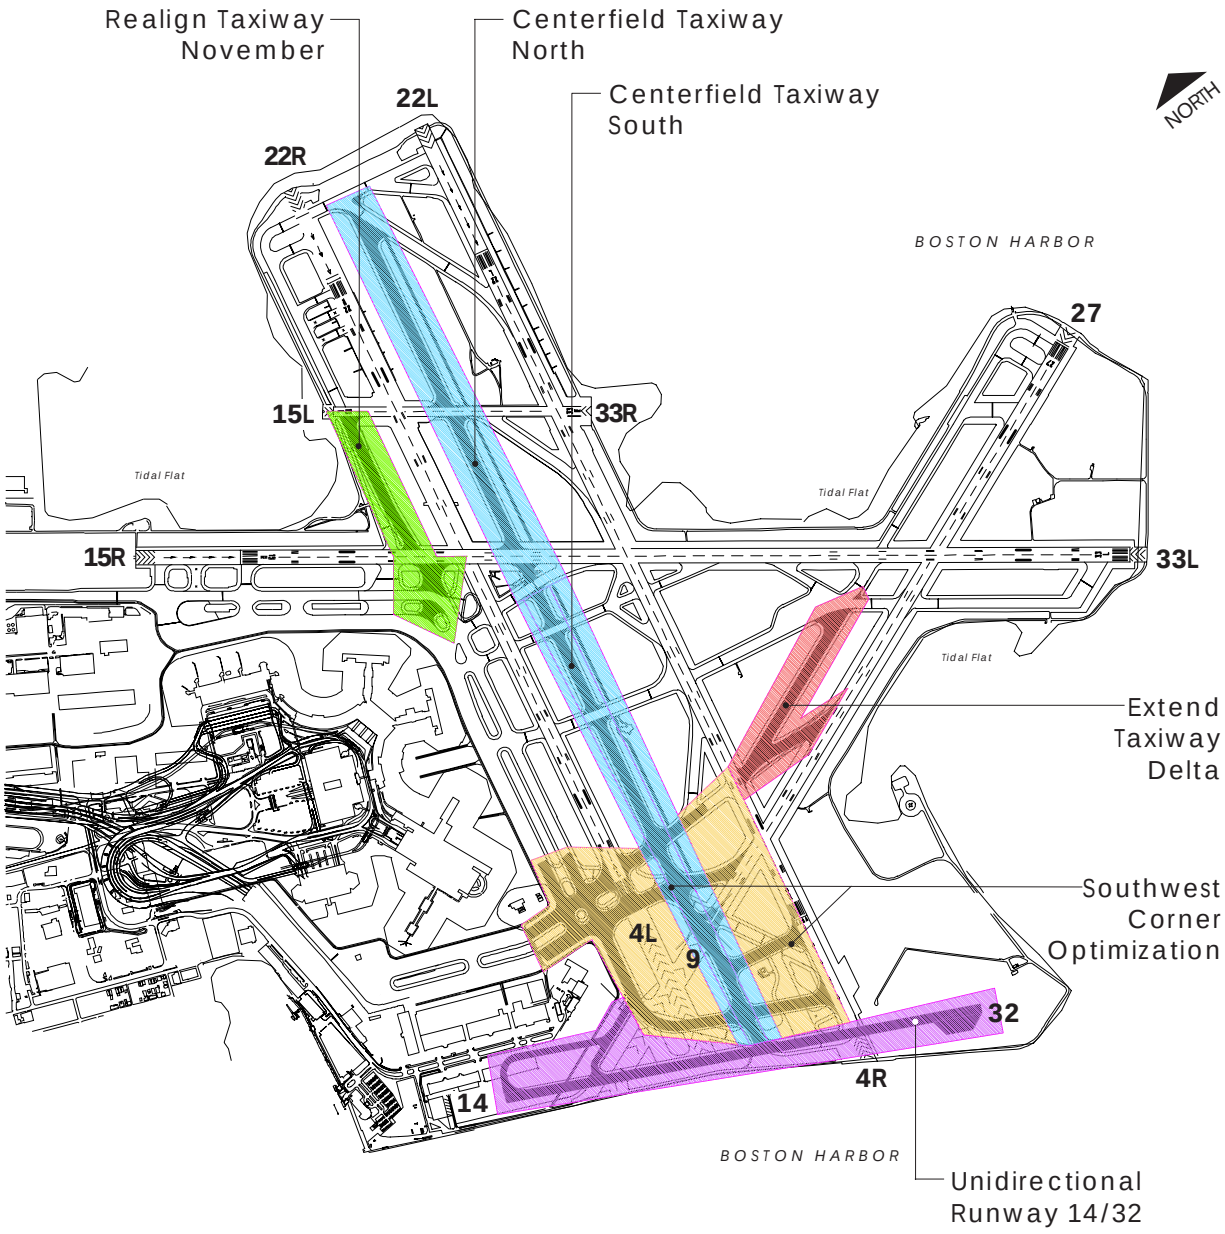

Figure 6.9-1

Year-By-Year Construction Activities - Alternative 1

7466-FIG-6.9-1.p65

6.9.3 Airfield Operations

Construction must not interfere with the ability of the existing airfield to efficiently process the tens of thousands of passengers who pass through Logan Airport on a daily basis. In addition, the safety of these passengers and airline crews during construction must be assured. The construction process has been planned bearing these two issues in mind.

A multi-year construction sequence will be employed to minimize potential disruptions on the airfield and to the staffing levels and work loads of ATC personnel. A Construction Phasing Plan, with these same goals, will be developed in close coordination with Massport Operations, and FAA control tower personnel. Massport will take the appropriate steps to ensure that all functions of the airfield continue to be provided in an efficient and safe manner during the construction period, and that any impacts to users that do occur are kept to a minimal level.

While the implementation of the Preferred Alternative presents challenges to Massport, Massport addresses such challenges frequently, as construction on and maintenance of the airfield are continuous Massport activities.

The operational and safety procedures which Massport and FAA have developed and employed successfully on past projects will be applied to the improvements proposed in the Airside Project.

6.9.3.1 FAA Regulations Governing Construction on Airfields

All construction activity at Logan Airport is governed by FAA Advisory Circular (AC) 150/5370-2C, Operation Safety on Airports During Construction. This document prescribes both general and specific measures to be employed during construction, including the following provision:

> *"Each bidding document (construction plans and/or specifications) for airport development work or air navigation facility (NAVAID) installation involving aircraft operational areas should incorporate a section on safety on airports during the construction activity. The section, as a minimum, should contain the appropriate provisions outlined in appendix 1 to this AC. (Para. 5b)"*

There is one guiding precept to the FAA regulations: aircraft operational and safety needs take precedence over construction. In practice, this translates to the following: construction activity adjusts both in location and in timing to airport runway configurations and taxiway patterns. In other words, runway configurations will not be altered to accommodate construction, except in instances where a number of runway configurations are available to the FAA personnel in ATC, and after coordination with FAA personnel as described below.

Massport follows FAA AC 150/5370-2C beginning with preliminary design and continuing throughout the construction period. A detailed safety section is presently included in all Massport bidding documents covering construction activity on the airfield, and such a section will be included in all construction bid documents (and subsequent construction contracts) for work on this project.

6.9.3.2 Airfield Operational Safety during Airside Project Construction

Preliminary Design

To minimize impacts on airfield operations, careful coordination would begin in the early stages of design to develop a coordinated Construction Phasing Plan for daily implementation. During the development of the Construction Phasing Plan, representatives from Logan Airport Operations, and the FAA will be consulted.

The Construction Phasing Plan would identify the following:

- a preliminary phasing plan, indicating the sequence of construction;
- construction areas, with nearby runways and taxiways and clearance requirements clearly demarked and highlighted;
- specific start and stop dates;
- hours and days of the week when the contractor is allowed to work within certain operationally sensitive areas of the airport;
- protocol and procedures for notifying FAA air traffic control personnel when an existing FAA NAVAID would be affected; and,
- preliminary construction traffic plan, indicating procedures and means of access/egress to/from the airfield and means of circulating within the airfield.

Construction of Runway 14/32 will entail the relocation of the Runway 27 localizer, a key element in the instrument landing system by the FAA. The localizer signal is used to establish and maintain an aircraft's horizontal position until the pilot makes visual contact with the runway. The Construction Phasing Plan will detail protocols and procedures to be followed when relocating and reinstalling this device. NAVAID closures will be coordinated with FAA air traffic control personnel, FAA safety personnel and Logan Airport Operations personnel. Notices to Airmen (NOTAMS) will be issued as appropriate. As necessary, FAA will broadcast information over the Logan Automatic Terminal Information Service (ATIS), describing areas of construction, NAVAID status, and closures or cautions on the use of runways and taxiways. As FAA ATC personnel update these radio broadcasts hourly, they provide pilots with a constant up-to-date status of construction activity on the airfield.

Construction

Once construction is underway, the contractor's performance for the previous week will be evaluated and discussions relevant to the work proposed for the following week will be included in the weekly job meetings and operations meetings held at Logan. Typically, these meetings are attended by representatives from Massport Logan Airport Operations, Capital Programs, FAA and contractors.

During these meetings, preliminary runway/taxiway closures or cautions would be discussed with Logan Airport Operations and FAA ATC personnel. As part of the requested closures or cautions, any interim taxi routing would also be discussed. Construction contingency plans would be prepared in case the contractor would not be allowed to work in the preferred location. All parties would agree with the proposed Construction Phasing Plan, which would then form the basis of the following week's construction activities.

The day-to-day decisions on whether a particular runway/taxiway would be available for construction work would be made by Logan Airport Operations and FAA ATC personnel. The following protocol would be utilized:

- Massport contacts FAA ATC personnel and requests applicable portion of the runway/taxiway (in accordance with the Construction Phasing Plan);
- FAA reviews wind and weather conditions, projected activity, and other factors and grants or denies request;
- If granted, Massport implements this decision and notifies the contractor accordingly; and,
- If denied, Massport implements this decision and notifies the contractor that work in another area of the airport, in accordance with the contingency plan established previously, would be required.
- Consistent with current Massport protocol, the public would be notified of changes in runway use during construction.

Under very poor weather conditions, Massport has the authority to deny or restrict the contractor's access to the entire airfield in which case, no work is done on the airfield.

Construction Vehicle Traffic Plan

The movement of construction equipment and trucks to and from the airfield construction site(s) is of particular concern to FAA and Massport. FAA notes that aircraft (and air passenger) safety is endangered by four principle causes: increased vehicle traffic volume, non-standard vehicle traffic patterns, vehicles without radio communications and marking, and operators untrained in the airport's safety procedures. Hence, according to FAA AC 150/5370-2C:

> *"...airport management must develop and coordinate a construction vehicle traffic plan with airport users, air traffic control and the appropriate construction engineers and contractors. This plan, when signed for all participants becomes a part of the contract." (AC 150/5370-2C, Appendix 1, para. 8)*

Such a vehicle traffic plan will be included in the Construction Phasing Plan developed by Massport for all construction projects on the airfield.

For both safety and security reasons, access to the airfield proper is available only through manned gates. For work on the south side of the airport (i.e., the southwest taxiway system, Taxiway Delta) the contractor would likely enter the airport through the existing South Gate located to the west of the airfield lighting vault (see Figure 6.9-2 for access points and circulation routes). From this point, the contractor would be escorted by licensed drivers approved by Logan Airport Operations in clearly marked contractor vehicles to the construction site using the airfield perimeter roadway. At critical junctures, such as the crossing of a runway or taxiway, Contractor licensed personnel request and receive permission from the FAA ATC prior to crossing.

For work on Runway 14/32, the contractor would typically use an existing construction-access gate located near the U.S. Postal Service facility (Building 61) on the south side of the airport. This access point provides a more direct access to the airfield perimeter roadway and has greater width to facilitate the turning of large trucks.

For all other construction projects, e.g., Taxiway November and the Centerfield Taxiway, access to the airfield would likely be through the North Gate. As per Massport's operating procedures, the contractor will be escorted to/from the construction site by trained personnel approved by Logan Airport Operations.

Contractor access locations will be verified during the development of the Construction Phasing Plan for the Airside Project improvements.

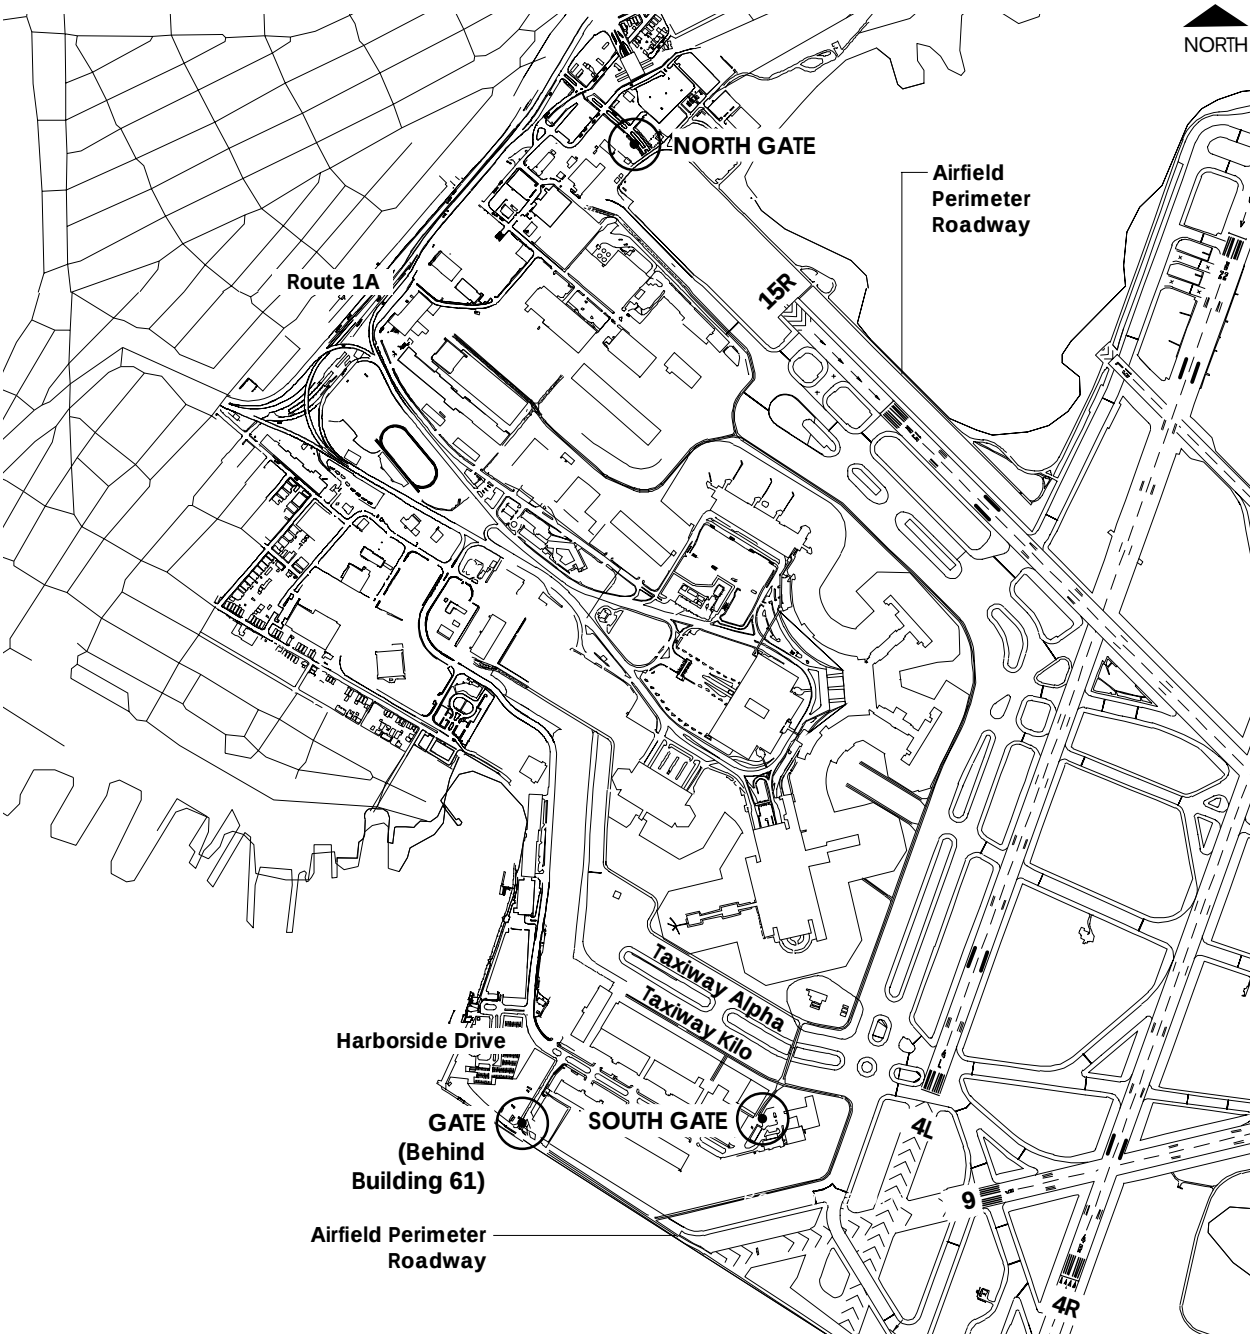

Figure 6.9-2
Airside Access Points

7466-FIG-6.9-2.p65

6.9.4 Impacts on the Surrounding Communities

For impacts other than those which might directly affect operations on the airfield, construction period impact assessments have been conducted with regard to existing ground transportation, air quality, noise and nighttime construction lighting. Each of these subject areas is discussed in the following sections of this chapter. Accompanying each of these assessments is a discussion of the mitigation measures that will be employed to minimize the impacts.

A variety of measures of activity have been developed in order to identify and mitigate the potential impacts of constructing the Preferred Alternative. These activity estimates are based on anticipated construction methods and projected construction schedules. Truck trips, the types of heavy construction equipment on the site, and the noise effects of similar construction projects are estimated. These data constitute key inputs to the construction impact analyses.

Average daily round-trip truck trip information was used in the assessment of ground transportation impacts and, in combination with estimates of heavy equipment use, in the noise impact assessment.

6.9.4.1 Ground Transportation

Impacts to ground transportation at Logan Airport during construction of the proposed airport improvements are not expected to result from the presence of construction-related vehicles (trucks or other heavy equipment) on the airport's roadway system. There will be no need to institute temporary detours for the main airport roadway as a result of the construction process. Roadway detours are only anticipated for the Perimeter Roadway on the airfield during construction of Runway 14/32, and a section of Harborside Drive in the South Cargo area during demolition of Cargo Buildings 60 and 61.

Construction-related Vehicles

The number of truck round trips required throughout construction of the Preferred Alternative is derived from the estimated quantities of construction materials to be brought to or removed from the site; bulk materials and equipment to be delivered to the site; truck capacity; quantity of excavate and building demolition debris to be removed; and production rate per workday.

The types of trucks included in the analysis are the following:

- Ten-wheel, tri-axle dump trucks (capacity of 10 to 15 cubic yards);
- Flat bed trailers to transport heavy construction equipment; and,
- Concrete trucks (capacity of 9 to 12 cubic yards).

The average daily number of truck round trips required to support the construction are depicted (by calendar quarter) in Table 6.9-5.

Table 6.9-5
Average Daily Truck Round Trips Per Quarter

Year/Quarter	Average Daily Round Trips	Daytime Trips	Nighttime Trips
2003 / 1st Quarter	61	61	0
2003 / 2nd Quarter	61	43	18
2003 / 3rd Quarter	61	61	0
2003 / 4th Quarter	61	61	0
2004 / 1st Quarter	--	--	--
2004 / 2nd Quarter	92	92	0
2004 / 3rd Quarter	92	46	46
2004 / 4th Quarter	92	92	0
2005 / 1st Quarter	--	--	--
2005 / 2nd Quarter	18	0	18
2005 / 3rd Quarter	18	5	13
2005/ 4th Quarter	18	5	13
2006 / 1st Quarter	--	--	--
2006 / 2nd Quarter	47	47	0
2006 / 3rd Quarter	47	38	9
2006 / 4th Quarter	--	--	--
2007 / 1st Quarter	--	--	--
2007 / 2nd Quarter	56	28	28
2007 / 3rd Quarter	56	28	28
2007 / 4th Quarter	--	--	--

These truck volumes should be viewed in the proper perspective: trucks will be prohibited from using local streets and thus will not impact local residential streets in communities surrounding the airport. Construction vehicles will be required to use state highways and / or main airport roadways, which are designated, truck routes. Vehicles with origins / destinations south of Boston would access the airport via the Ted Williams Tunnel and the Haul Road, or other designated haul routes, with access to I-93. Vehicles traveling to / from the north would use Route 1A. (See Figure 6.9-3.)

Construction traffic from the improvements associated with the Preferred Alternative would not add significantly to the existing volume of traffic using these roads. Peak airside truck traffic

is estimated to be approximately 184 truck trips per day.[40] This is reduced significantly from 648 peak truck trips presented in the Airside Project Draft EIS/EIR as a result of the reduction of soil material to be removed off-site. Average weekday traffic on the major highways accessing Logan Airport in 1998 was approximately 113,300 vehicles.[41] Construction vehicles associated with the Airside Project represent less than 0.2 percent of the total traffic volume and will not have a significant impact on the regional highway system.

Traffic Operations

During the multi-year construction of the Airside Project improvements, Massport will seek to maintain the full operation of Harborside Drive at all times. As necessary, temporary roadways will be constructed prior to the disruption or closure of existing airfield roadways. (Access to airfield roadways is restricted to authorized vehicles only.) Police details will be employed at appropriate locations on the airport to manage traffic and ensure public safety.

6.9.4.2 Air Quality

Construction-related activities can result in short-term impacts on ambient air quality. These potential impacts include increased emissions from motor vehicles on the airport roadways, direct emissions from construction equipment, and fugitive dust emissions. The latter can occur during ground excavation, movement of equipment at the site, and transport of material to and from the site. Fugitive dust during periods of intense activity can present a problem, particularly in windy or dry weather conditions, although the problem is localized.

During the construction process, a regular program of street sweeping will minimize dust from movements of construction vehicles on airport roads. Fugitive dust will also be controlled with water spray as needed during demolition and construction; no chemical soil stabilizers will be used. To the extent it is safe, practicable, and feasible within the airfield environment, fencing will be used around the perimeter of demolition and construction areas to shield the public from fugitive dust and to help contain fugitive dust within the construction area. All trucks hauling demolished and excavated materials from the site will be covered and truck wheel wells will be washed before leaving the site. Because of these mitigation measures and the distance from the construction site to the nearest residential neighborhood, it is projected that fugitive dust from construction of the Airside Project improvements will not impact the surrounding communities.

▼

40 92 round trips equal 184 total trips.

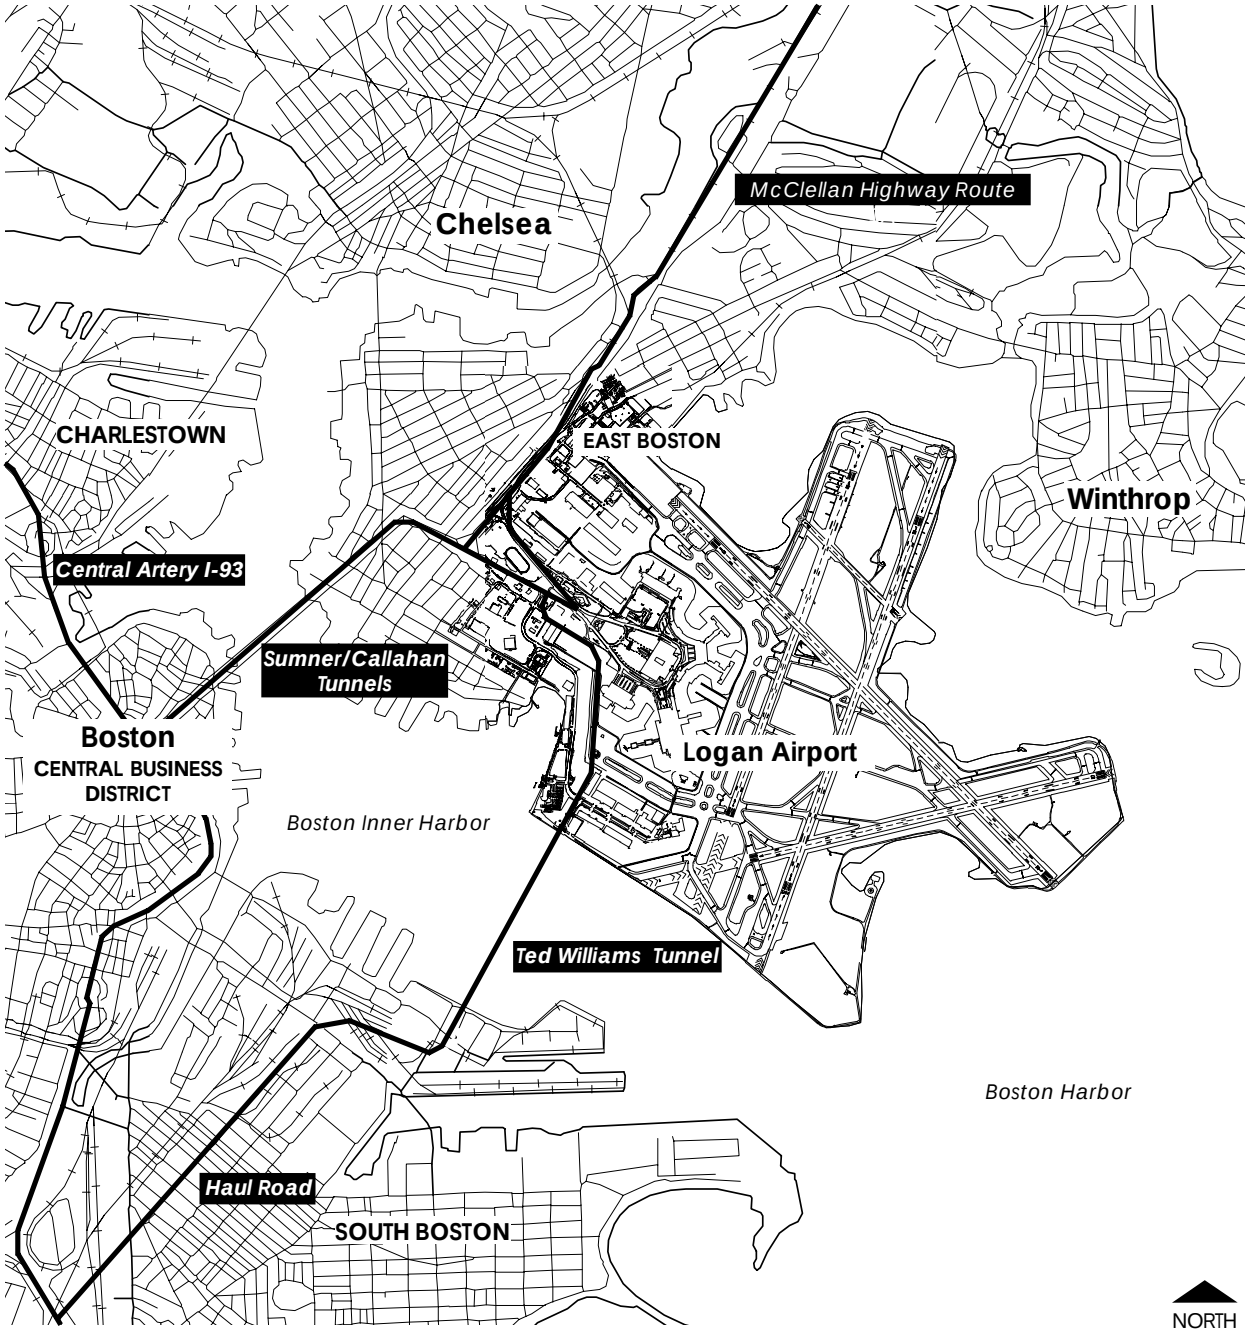

Figure 6.9-3
Proposed Construction Traffic Routes

7466-FIG-6.9-3.p65

Airborne particulate matter such as dust is measured by monitoring ambient PM-10 (particulate matter less than 10 microns in diameter). The closest PM-10 monitoring station, and the one most representative of the project site, is at 340 Bremen Street, East Boston. Published data from DEP (for the year 1998) indicate that the second highest maximum 24-hour PM-10 level measured at this monitoring station was 49 micrograms per cubic meter ($\mu g / m^3$). The 24-hour NAAQS for PM-10 is 150 $\mu g / m^3$, which is a level set to protect public health and welfare. It is expected that total levels of particulate matter will remain in compliance with the NAAQS during construction, since the existing worst-case PM-10 concentration is only 33 percent of the health standard. This will be ensured through the mitigation measures discussed above.

Emissions from all construction equipment, including those listed below in Section 6.9.4.4, were quantified by year using appropriate emissions factors from the EPA models. MOBILE5a_H and PART5 were used with inputs provided by MADEP to determine emission factors for diesel and gasoline trucks at a speed of 15 miles per hour (e.g., asphalt tanker trucks and stake trucks), while NONROAD (draft) was used to determine non-road emissions (e.g., demolition hammers, backhoes, graders, etc.). The emissions factors in this model incorporate national averages for equipment loading factors and engine horsepower. The activity levels (hours per year) and emissions associated with each equipment type are contained in Appendix J.

Paving activities associated with the airfield projects have associated emissions of VOCs, which are components of asphalt. These emissions have been quantified and are included in the summary of construction-related air emissions in Table 6.9-6.

Table 6.9-6
Construction-Related Air Emissions in Tons per Year (tpy)

Year	VOCs	NOx	CO	PM
2002	19.98	34.34	72.52	2.56
2003	29.40	25.53	50.58	1.64
2004	30.39	9.82	35.81	0.86
2005	7.11	5.79	20.88	0.41
2006	7.83	7.95	20.98	0.61

Note: *De minimis* values for VOCs and NOx are each 50 tons per year (tpy); 100 tpy for CO. No *de minimis* levels apply for PM because the area attains the standards for this pollutant.

As shown, emissions of VOCs, NOx, and CO are all below the *de minimis* rates that would trigger a Clean Air Act conformity determination. Furthermore, Massport is committed to implementing the Clean Air Construction Initiative in cooperation with MADEP and Northeast States for Coordinated Air Use Management (NESCAUM). This program is currently in place for the Central Artery/Tunnel, where conversion of

25 percent (70 pieces) of construction equipment will reduce emissions of hydrocarbons (or VOCs), CO, and particulate matter (PM). NESCAUM studies show that use of an oxidation catalyst, which may also be used in conjunction with a fuel-borne catalyst, can reduce, on average, VOCs by 42 percent, CO by 31 percent, and PM by 23 percent. Use of a particulate filter can reduce PM by 81-96 percent and, when the filter is coated with an oxidation catalyst, CO and VOCs can be reduced by 66 percent. None of the tested technologies has had an effect on NOx emissions. The reductions attributable to this initiative have not been incorporated into the results in Table 6.9-6 above, and they would have the effect of further reducing emissions below *de minimis* thresholds.

6.9.4.3 Noise

The assessment of construction noise impacts was based on the following primary inputs:

- The quantity of heavy construction equipment anticipated to be used during construction;
- The number of truck trips to or from each construction area;
- The location of the proposed construction on the airfield; and,
- The amount of night time and day time construction.

The number of truck trips is as developed in Section 6.9.4.1. The other levels of activity are derived as described below.

6.9.4.4 Heavy Construction Equipment

Estimates of the number of pieces of heavy construction equipment in use at the site were based on such factors as the productivity rate per workday and the duration of construction. The types of equipment expected to be utilized are listed below and are described in greater detail in Appendix J. The average daily number of pieces of equipment scheduled to be used for the calendar quarter and daytime and nighttime construction also is provided in Appendix J.

- Dump trucks
- Mobile cranes
- Graders
- Concrete trucks
- Front end loaders
- Pavement milling machines
- Liquid asphalt tanker truck
- Compressors
- Pavements saws
- Tractor-trailers (materials)
- Backhoes
- Demolition hammers
- Back hoes with hoe-rams
- Generator
- Compactors
- Excavators
- Sweepers
- Bulldozers
- Paving machine

6.9.4.5 Construction Period Noise Analysis

Analysis Summary

The construction period noise analysis evaluates the potential noise impact from the Airside Project on the closest noise-sensitive areas to the construction zone and follows the methodology used previously for the West Garage and International Gateway environmental analysis. Potential construction noise impacts were evaluated at the following receptor locations:

- Receptor 6 Somerset and Johnson, Winthrop
- Receptor 7 Loring Road near Court, Winthrop
- Receptor 10 Bayswater / Shawsheen, East Boston
- Receptor 12 East Boston Yacht Club, East Boston
- Receptor C[42] Coleridge Street Residence, East Boston
- Receptor A Sumner near Lamson, East Boston
- Receptor 14 Jeffries Point Yacht Club, East Boston
- Receptor E Farragut Road at Second, South Boston

Predictions of average daily equivalent (Leq) and day-night equivalent (DNL) noise levels were made for each receptor.

Noise impact may result from annoyance and activity interference due to the operation of a variety of heavy construction equipment and trucks used to transport construction materials and equipment to and from the site. A number of mitigation measures are proposed in the construction noise mitigation discussion below.

Because environmental noise fluctuates from moment to moment, it is common practice to condense all this information into a single number, called the “equivalent” sound level (Leq). Leq can be thought of as the steady sound level that represents the same sound energy as the varying sound levels over a specified time period; it accounts for all the noise that occurs during this period. Many surveys show that Leq properly predicts annoyance, and thus this metric is commonly used for the assessment of cumulative noise impact. For the purposes of this study, Leq is evaluated over an average daily 8-hour construction shift during each quarterly construction period. The analysis of Leq was conducted for both the daytime and nighttime construction periods. Criteria for evaluating construction noise impact in terms of Leq are described below.

The day-night equivalent level (DNL) measures noise over a 24-hour period. It is calculated in the same manner as a 24-hour Leq, except that noise that occurs in the nighttime (defined as 10:00 PM to 7:00 AM) is penalized by 10 dB to account for peoples’ increased sensitivity to nighttime noise.

▼

42 Same as “Receptor E” in International Gateway, EIR/EA, October 15, 1996.

Potential construction noise impact associated with the Airside Project was assessed in terms of average daytime equivalent sound levels, average nighttime equivalent sound levels, and day-night equivalent level, using criteria based on the existing noise environment as well as applicable standards. A summary of the analysis method is provided below, including descriptions of the noise measures, criteria, and modeling methods used. Detailed input and output data for the construction noise projections are provided in Appendix J.

The results of the construction period noise analysis indicate that, under worst-case conditions, no perceptible construction noise impact during the daytime or nighttime construction period is expected within the community as a result of the Airside Project.

Analysis Conditions

The potential noise impacts associated with the Airside Project construction activities were evaluated on a quarterly basis over the proposed five-year construction period (2002 to 2006). During each quarterly period, potential noise impacts were evaluated on a worst-case basis, based on the projected average daily heavy construction equipment usage and truck operations and whether construction occurred during the day time or night time. For the purpose of impact assessment, ambient noise conditions were based on existing information from noise monitoring stations maintained by Massport.

For noise analysis purposes, all construction activities related to the Airside Project were divided into two construction locations: those on the north side of the airfield which would use the North Gate for construction access, and those on the south side which would use the South Gate or Construction Gate for access (see Figure 6.9-2). The dividing line between the two construction areas was defined as Runway 15L / 33R.

A cumulative assessment of construction noise for all significant construction at Logan Airport during the 2002 to 2006 timeframe of Airside Project improvements construction is presented in Chapter 7.

Noise Impact Criteria

Criteria for the assessment of construction impacts from the Airside Project are based on consideration of applicable federal standards. Although there are no specific federal criteria for construction noise impact assessment, most federal agencies (including the Environmental Protection Agency (EPA), Housing and Urban Development (HUD), Federal Aviation Administration (FAA), and Federal Highway Administration (FHWA)) recommend the use of Leq-based noise descriptors for general assessments of noise impact. The relevant provisions of federal standards that apply to construction noise are summarized below.

The 1990 CA/T *Final Supplemental EIS/R* and *Supplemental Final Section 4(f) Evaluation* evaluated the noise impacts of the CA/T Project construction based on FHWA standards. The following excerpt from that document provides a discussion of noise impact criteria:

> *"FHWA recognizes that an adverse, or substantial, noise impact occurs when existing noise levels are exceeded by more than 15 dBA. Increases of less than 15 dBA over existing levels may be classified into one of three subjective impact categories, depending on the extent of the increases. Less than a 5 dBA increase would be categorized as 'no impact.' A 5 to 9 dBA increase would be considered a 'minor impact,' while a 10 to 15 dBA increase over existing levels would be a 'moderate impact.' "*

For the Airside Project and concurrent construction projects at Logan, noise impact is assessed on a relative basis, as an increase over existing ambient noise level at each receptor, in a manner consistent with the CA/T Project.

These descriptors thereby allow a meaningful comparison of project noise and ambient noise, and provide a means to evaluate cumulative noise impact from concurrent projects. Furthermore, the results of attitudinal surveys of noise impact have shown that Leq-based descriptors correlate with annoyance better than any other descriptors. For these reasons, the assessment of noise impact from constructing the Airside Project is based on Leq according to the federal standards described above. Projections of day-night equivalent noise levels are provided as additional information to help evaluate the effect of nighttime construction.

Off-Airport Noise During Construction

Quarterly construction noise projections are provided in Tables 6.9-7, 6.9-8, and 6.9-9 for receptor locations 6, 7, 10, 12, 14, A, C, and E. These tables compare the projected average daily DNL and Leq for day and night during each quarterly construction period for the Airside Project to the existing ambient noise. Noise impact is assessed based on the projected increases above the ambient noise level. These increases represent worst-case conditions that are expected to occur intermittently, based on wind direction, in any quarter.

The results of the construction period noise analysis indicate that during construction, the average daily DNL at the receptor locations ranges from 0.5 dB to 3.0 dB over ambient noise levels. The Leq during construction ranges from 0.4 dB to 2.0 dB over ambient noise levels during the daytime construction period and 0.5 dB to 3.9 dB over ambient noise levels during the nighttime construction period. All increases in noise associated with construction of the Airside Project are less than 5 dB, and therefore are considered to have "no impact" according to FHWA standards.

The noise increases projected as a result of Airside Project construction range from 0.4 dBA to 3.9 dBA with respect to the ambient level. Based on the FHWA criteria described above, no impact is predicted at any of these residential sites.

On-Airport Noise Assessment

The quantitative noise analyses presented above address potential impact to community areas outside the airport. Given the ambient noise level at the airport and the fact that construction will occur on the airfield and away from the terminals, it is not likely that construction noise would be audible to airport patrons. Because the terminal buildings are designed to reduce noise from outside sources (in particular from aircraft) construction noise should not be intrusive to patrons inside the terminals.

6.9.4.6 Nighttime Construction Lighting

Area lighting will be required for nighttime construction. Contractors would be required to aim the lights on the construction site and away from the neighborhoods, pilots and control tower.

The typical lighting device is a light station mounted on a trailer with a generator. The generator has a muffler to minimize the engine noise. Once at the construction site, the light station is extended above the trailer to an overall height of approximately 10 to 15 feet, aimed toward the construction area and turned on. At the end of the nighttime period, the light station is lowered onto the trailer and the generator stopped. The entire unit is then transported to the contractor's equipment storage area.

The number of light stations will depend on the size of the work site. A maximum of eight light stations would normally be used during paving operations.

6.9.5 Construction Mitigation

An extensive array of construction period mitigation measures is proposed for the proposed Airside Project improvements. Measures specifically addressing safety, traffic, air and water quality, light and noise will be written into the contract documents and specifications governing the contractors and subcontractors constructing the improvements. As in Logan Airport Modernization and other major construction projects at the airport, Massport will employ a team of on-site resident engineers and inspectors to monitor the contractors' compliance with these mitigation measures.

Safety is of paramount concern since major construction will be occurring in proximity to operating runways and taxiways. All construction activity will be governed by the requirements of FAA AC 150/5370-2C Operational Safety on Airports During Construction.

Construction mitigation measures in a number of categories are described below.

6.9.5.1 Traffic Operations

During the construction of the proposed Airside Project improvements, Massport will seek to maintain the full operation of the airport roadway system at all times. If and as

necessary, temporary roadways will be constructed prior to the disruption or closure of the South Cargo area section of Harborside Drive as well as the existing airfield roadways, with current lane capacity being maintained to the maximum extent feasible.

Specific traffic mitigation measures to be employed will include, but not necessarily be limited to, the following:

- Construction vehicles will be required to use State highways or Logan Airport roadways, including the Ted Williams Tunnel, except for access to the North Gate or when seeking access to local businesses. A clause to this effect will be inserted in all construction contracts relating to the Airside Project improvements.
- Truck routes for Logan Airport projects are established which minimize impacts on the local communities. Construction vehicles would be restricted from using Neptune Road (except to access the North Gate), Maverick Street, and Porter Street in East Boston. Designated truck routes will be specified in all construction contracts.
- No construction employee parking spaces will be permitted on the construction site nor will provisions be made for them elsewhere on-airport with the exception of a small number of spaces for supervisory personnel. It is expected that construction workers will access the airport via public transportation or via shuttle buses from off-airport parking areas.
- Police details will be employed at appropriate locations on the airport to manage traffic and ensure public safety.

6.9.5.2 Air Quality

As part of its continued commitment to reduce impacts to the environment, Massport will require contractors to retrofit their heavy construction equipment with advanced pollution control devices during construction in accordance with DEP's Clean Air Construction Initiative. Contractor-owned equipment such as front-end loaders, backhoes, cranes and excavators will be retrofitted with oxidation catalysts. This device filters out and breaks down hydrocarbons, particulate matter and carbon dioxide associated with diesel emissions. Contractors would also have the option of using alternative fuel vehicles.

Additionally, air quality impacts will be minimized using the following techniques:

- During the construction process, a regular program of street sweeping will be employed to minimize dust from construction vehicle movements on airport roads.
- Fugitive dust also will be controlled with water spray as needed during demolition and construction; no chemical soil stabilizers will be used.
- All trucks hauling demolition materials and excavate from the site will be covered. Truck wheel washing will be performed prior to vehicles leaving the site to help suppress fugitive dust.

6.9.5.3 Noise

General construction noise will be limited using techniques such as:

- Use of concrete crushers or pavement saws for building demolition or similar construction activity;
- Use of local power grid to reduce the use of generators, to the extent practicable and feasible.
- Attaching: (1) intake and exhaust mufflers, shields, or shrouds; (2) noise-deadening material to inside of hoppers, conveyor transfer points, or chutes.
- Limiting: (1) the numbers and duration of equipment idling on the site; (2) the use of annunciators or public address systems; (3) the use of air or gasoline-driven hand tools.
- Configuring, to the extent feasible, the construction site in a manner that keeps loud equipment and activities as far as possible from noise-sensitive locations.

When construction is scheduled during the nighttime hours and near the community sensitive areas (i.e., Bayswater, Winthrop) the following noise mitigation measures will be employed:

- The use of backup alarms for all pieces of equipment will be prohibited. The Contractor will be required to provide additional laborers to assure that equipment backup is safe and complies with OSHA regulations.
- Trucks delivering bituminous concrete or other materials will be prohibited from slamming their tail gates to clean out the beds of their trucks after dumping.
- During paving operations, the contractors will be required to turn off their vibratory compactors prior to exiting off of the newly placed pavement and onto the old existing pavement.

Further noise control options will be evaluated when the project design commences to define their effectiveness and feasibility. Appropriate operational specifications and performance standards will be incorporated into the construction contract documents.

6.9.5.4 Water Quality

A site-specific Stormwater Pollution Prevention Plan (SPPP) will be required of all contractors in accordance with EPA regulations to mitigate water quality impacts and to keep the airport's existing stormwater system free of sediment and contaminants during construction. The SPPP will be developed as part of the construction NPDES permit.

In accordance with the SPPP, extensive siltation controls will be installed prior to the commencement of construction and maintained until the project area is fully stabilized. Because of the airfield's flat topography, erosion is more controllable than on more variable topography. Precipitation falling on or running into the excavation area will be

collected at sumps and pumped to stormwater and dewatering detention tanks. The siltation controls will include, but not be limited to, siltation fencing, haybales, haybale checkdams, temporary seeding, inlets controls and regular Best Management Practices (BMP) inspections.

6.9.5.5 Overall Project Construction Mitigation

In addition to the specific measures cited above, Massport has developed a number of mandatory construction mitigation procedures for all construction contractors. Massport will be responsible for overseeing all activities related to the proposed Airside Project improvements including the following management practices:

- Full coordination with the CA/T Project, and with all relevant agencies including the FAA, MBTA, Massachusetts Turnpike Authority, Massachusetts DEP, Massachusetts CZM, Massachusetts Water Resources Authority (MWRA), City of Boston, Boston Water and Sewer Commission (BWSC), and utility companies, as appropriate.
- Preparation of detailed pre-construction plans for traffic maintenance, construction specifications for contractors, and coordinated scheduling of all construction activities (as well as the other measures noted in the ground transportation section above).

General construction practices will be established by Massport for all work to be performed on the Airside Project. These practices will incorporate in the contract specifications the following elements:

- Hours of work generally will be limited to typical working hours of 7:00 AM to 3:00 PM, when feasible and practical, depending on traffic and travel conditions. When necessary, as in the construction of Runway 14/32, a second shift will be employed with typical working hours of 3:00 PM to 11:00 PM. There are periods, however, when construction at night and/or on weekends when airfield activity is low, is the most appropriate and safe period for construction. Such periods are the crossing of major runways and taxiways, and construction of the Southwest Taxiway system. This night and weekend activity will serve to reduce the overall duration of the heavy construction period.
- An additional shift between 11:00 PM Friday and 2:00 PM Sunday may be scheduled when the contractor has to work within operationally sensitive areas. In these instances, the contractor will be required to concentrate on one isolated location on the airfield to complete all of the required work within the 39 hours allocated. Construction activities involving the existing runways and taxiways would occur during this construction shift.
- A list of construction Do's and Don'ts will be distributed to all construction workers during pre-construction orientation meetings. This simple set of guidelines and rules (developed in concert with the local East Boston community) will help keep the construction program safe, efficient, and non-disruptive.
- As previously noted, all trucks will access the site by the main airport roadways and the Ted Williams Tunnel only. Use of the Haul Road through South Boston will further limit

truck traffic on local streets. Trucks will be prohibited from using local streets, except for a short section of Neptune Road that provides access to the North Gate or by contractors when seeking access to local businesses.

- A transportation management plan will be required of the contractor. Subject to the review and approval of Massport, this plan will describe how the contractor intends to comply with the on-airport employee parking restrictions set by the terms of the Airside Project improvements construction contract.
- Fugitive dust will be controlled through wetting, sweeping, and other dust suppression techniques. Massport will require contractors to maintain on-site water trucks. All trucks hauling materials and excavate from the site will be covered.
- Soils borings, testing and environmental characterization in the area of the proposed project will be conducted.
- A Soils Use Policy will be developed. Based upon the practices and procedures of a soils management plan similar to that developed for Logan Airport Modernization, as well as a detailed program of subsurface investigations in the airfield, the plan will outline standards and procedures for the identification, handling and disposal of contaminated materials that may be encountered on the airfield. Soil tracking protocols will be detailed from the point of excavation to designated stockpile areas and to the ultimate disposal site.
- A Health and Safety Plan similar to that developed for Logan Airport Modernization will be adapted to establish the minimum health and safety standards that contractors must meet during construction on the airfield. This includes requirements for environmental monitoring, personal protective equipment, site control and security, and training.
- Massport will work with the contractor to encourage the recycling of materials, including construction debris from the demolition of Buildings 60 and 61, pavement grindings and suitable excavate, during construction of the airfield improvements.

6.9.5.6 Agency and Community Coordination

In order to ensure that all best efforts to mitigate construction impacts are continued throughout the construction process, Massport will carry out the following ongoing mitigation efforts:

- Placement of personnel and equipment to monitor and report on the status of construction, construction-related impacts, and the effectiveness of mitigation measures.
- Creation of specific construction-related performance standards for incorporation in construction contracts.
- Publication of periodic community newsletters advising the public as to the status of the project.

6.10 Adverse Impacts Which Cannot Be Avoided

Implementation of the Preferred Alternative will reduce the population within the 70 and 75 dB DNL noise contour but is predicted to increase the noise-impacted population within the 65 dB DNL noise contour by about 2 percent. Affected residences will be sound insulated to mitigate this impact. Measures will also be employed to mitigate impacts to the tenants of Cargo Building 60 that will be displaced by construction and to provide off-site habitat enhancement for the upland sandpiper habitat that will be lost due to construction of the Centerfield Taxiway.

6.11 Short-Term Uses and Long-Term Productivity

Logan Airport is an important element in the regional transportation network and a key factor in the economy of New England. Implementation of the Preferred Alternative, which includes Runway 14/32, will improve the efficiency, safety and reliability of current and projected operations at Logan. No other viable Alternative that would accomplish the goals of the Preferred Alternative exists. The Preferred Alternative would reduce annual runway delays and virtually eliminate delay associated with northwest wind conditions. Construction of Runway 14/32 increases the FAA's runway selection options to the extent that the achievement of PRAS goals is predicted to nearly double compared to the No Action Alternative. Similarly, by increasing operations over water, Runway 14/32 reduces the total annual hours of dwell and persistence over populated areas in accordance with short-term PRAS goals. As a result, the Preferred Alternative would be effective in reducing the population in severely impacted communities within the 70 and 75 dB DNL noise contours.

As noted in preceding sections of this Supplemental DEIS/FEIR, the impacts associated with the Preferred Alternative include: the dislocation of the tenants of Cargo Building 60, a two percent increase in the population within the 65 dB DNL noise contour, and the loss of approximately 37 acres of upland sandpiper habitat. An extensive series of mitigation measures and commitments are proposed to address these impacts, including the provision of relocation assistance to the cargo building tenants in accordance with applicable laws and sound insulation of affected residences within the 65 dB DNL noise contour. Sound insulation of the few historic residential properties within this contour will be undertaken in accordance with standards established by the Secretary of the Interior (36 CFR 800.5(b) – see Appendix H for a copy of the letter from the Massachusetts Historical Commission, December 21, 1999.) A Conservation and Management Plan has been developed to provide a long-term net benefit to the upland sandpiper population, including off-site restoration of 150 acres of habitat.

In consideration of the benefits to be derived from the Preferred Alternative and the measures to be employed to mitigate impacts, the short-term use of resources required to implement the proposed action is consistent with the long-term goal of improving the efficiency and reliability of airside operations at Logan.

6.12 Irreversible and Irretrievable Commitment of Resources

Implementation of the Preferred Alternative would require certain irreversible and irretrievable commitments of resources; however, there are no new, unusual, or limited sources of materials associated with the Preferred Alternative. Construction of the runway and taxiway improvements will consume fuel and result in the consumption of raw materials such as gravel, concrete and other materials required for the construction process. Materials from demolition of existing structures will be recycled to the extent possible. There are no materials required for the construction or operation of the Preferred Alternative that are known to be in short supply. Although there will be some impacts to natural resources, measures will be implemented to mitigate both short-term (construction) and long–term impacts to the greatest extent practicable.

7 Cumulative Impacts

Key Points

In the Airside Improvements Planning Project Draft Environmental Impact Statement / Environmental Impact Report (Airside Project Draft EIS / EIR), Chapter 7 presented an assessment of incremental environmental impacts of the alternatives in the context of other landside projects and identified the interrelationships / independence of Massport's airside and landside initiatives. This chapter of the Supplemental Draft EIS / Final EIR (DEIS / FEIR) presents an updated construction management plan that quantifies the number of daily and total truck trips and includes construction activity that will occur simultaneously with the Central Artery / Tunnel construction in East Boston, other Logan Airport projects, and any other major construction activities planned to occur in East Boston.

- The Logan Airside Improvements Planning Project (Airside Project) has independent utility, and will not stimulate, preclude or otherwise determine other development anticipated as part of Massport's landside planning efforts. The Airside Project is needed whether or not passenger levels at Logan International Airport (Logan) continue to grow.
- The Airside Project noise assessment is cumulative by its nature, examining all aircraft operations, including in-flight as well as ground taxi noise. By reducing delay and increasing the ability to meet Preferential Runway Advisory System (PRAS) goals, the Preferred Alternative (Alternative 1A) provides a significant reduction in noise for the most severely impacted areas. After sound insulating to mitigate impacts within the 65 decibel (dB) day-night sound level (DNL) noise contour, the Preferred Alternative provides net long-term benefits.
- There are no significant aircraft noise impacts associated with the operation of the other present and reasonably foreseeable landside projects at Logan, and therefore no cumulative noise impacts created by the combination of these projects with the proposed Airside Project improvements. The future fleet forecasts and airport operations associated with the proposed terminal improvements at Terminal B and Terminal E, and the proposed replacement of Terminal A, are consistent with the analysis assumptions made for the Preferred Alternative.
- There are no long-term cumulative air quality impacts. The Airside Project air quality assessment evaluated cumulative impacts associated with all airport-related sources of air emissions, including on- and off-airport motor vehicles. Results indicate that overall air quality impacts are beneficial or will remain within the National Ambient Air Quality Standards (NAAQS).

- A cumulative air quality benefit is achieved as a result of the net effect of the Airside Project, the Logan Modernization landside projects, and the Central Artery/Tunnel (CA/T) improvements, which independently produce positive air quality benefits.

- Construction traffic from the proposed Airside Project improvements associated with the Preferred Alternative would not add significantly to the existing volume of traffic. Peak airside project truck traffic is estimated to be approximately 184 trips per day.[1] This is reduced significantly from 648 peak truck trips presented in the Airside Project Draft EIS/EIR as a result of the reduction of soil material to be removed off-site. Construction vehicles on Logan associated with the Airside Project represent less than 0.2 percent of the total traffic volume and will not have a significant impact on the regional highway system.

7.1 Introduction

As the discussion in the preceding chapters demonstrates, Logan Airport is a multi-faceted facility that involves a wide variety and level of transportation-related operations that have various environmental impacts. From both functional and environmental impact perspectives, Logan can be divided into two components: landside facilities and airside facilities. Functionally, the landside facilities are those which accommodate the ground movement of passengers to-and-from Logan and to-and-from aircraft. Landside facilities consist primarily of roadways, vehicular parking lots and garages, passenger terminals, and airport service areas. The primary functions of the airside facilities are to accommodate aircraft operations (i.e., landings and takeoffs) and movements (i.e., taxiing). The airside facilities consist of Logan's runways, taxiways and apron areas.

Analysis and consideration of both project-specific and cumulative environmental impacts are important elements in the Massachusetts Port Authority (Massport) process for identifying and, where appropriate, recommending and implementing capital improvement projects. For those project concepts which meet certain established regulatory threshold criteria, the environmental evaluation process is formalized through appropriate documents prepared and submitted for public review in accordance with both federal law (the National Environmental Policy Act (NEPA) as amended), and pertinent implementing regulations and agency orders, and state law (the Massachusetts Environmental Policy Act (MEPA) as amended), and pertinent implementing regulations.

Environmental review of Logan Airport operations takes place at two levels. The first is a comprehensive, cumulative analysis in the form of the state required Logan Airport Generic Environmental Impact Report (GEIR) now known as the Logan Airport Environmental Status and Planning Report (ESPR), and associated Logan Airport Annual Updates, now known as Environmental Data Reports (EDRs). The GEIR/ESPR cycle, which includes the *1994/95 GEIR*, *1996 Annual Update*, *1997 Annual Update*, and the *1998*

1 92 round trips equal 184 total trips.

Annual Update, and the recently submitted *1999 ESPR* (i) presents annual environmental conditions for noise, ground access, air quality and water quality, and assesses the cumulative impacts of current and predicted levels of the various types of operations on both the landside and airside facilities; (ii) reports on the status of planning, design, and construction activities at Logan, and (iii) presents and tracks Massport's mitigation commitments. The GEIR/ESPR provides context to on-going planning at Logan and is intended to enhance Executive Office of Environmental Affairs' (EOEA's) and FAA's review of individual project concepts.

The second level of environmental review is project specific. Potential improvement projects that proceed from the planning to the proposal stage are also subject to individual project NEPA and MEPA review if such projects fall within established guidelines. The level of such review varies, and may include initiating a federal Environmental Assessment (EA) or Environmental Impact Statement (EIS) in anticipation of Federal Aviation Administration (FAA) funding or layout plan approval, and/or filing an Environmental Notification Form (ENF) to initiate the state review process that may include the preparation of an Environmental Impact Report (EIR). The focus of individual project review centers on the comparative analysis of impacts/benefits associated with various project alternatives, including the Preferred Alternative and a No Action Alternative. Both federal and state individual project review also includes consideration of project impacts within a cumulative project impact context.

This Airside Project Supplemental DEIS/FEIR assesses cumulative environmental impact in accordance with Council on Environmental Quality (CEQ) regulations and guidance[2] and FAA implementing directives, as well as the MEPA regulations, respectively. CEQ defines cumulative impact as that "which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions..." (CEQ, 40 CFR 1508.7). In determining the scope of environmental documents with regard to cumulative impact, the CEQ requires that agencies consider actions which may be "connected" (i.e., actions that automatically trigger other actions, cannot proceed in the absence of other actions, or are interdependent parts of a larger action), "cumulative" (i.e., when viewed with other actions have cumulatively significant impacts), or "similar" (i.e., when viewed with other reasonably foreseeable or proposed actions have similarities that provide a basis for evaluating their consequences together.) This information is provided in Section 7.3.

The purpose of the Airside Improvements Planning Project is to address aircraft operating delays and to enhance the safety of the Logan airfield. The proposed Airside Project improvements focus on improving the efficiency of aircraft operations. These proposed airside improvements serve a functionally different purpose than the many different landside projects that are designed to improve the ground access of passengers to and from Logan and to and from aircraft, or to improve passenger processing and services.

2 "Considering Cumulative Effects Under the National Environmental Policy Act," Council on Environmental Quality, January 1997.

The Airside Project has independent utility, and will not stimulate, preclude, or otherwise determine other development anticipated as part of Massport's landside planning effort. None of the past, present, or foreseeable future projects described in Section 7.3 are functionally or economically interdependent with the proposed Airside Project. The project will not foreclose future options or irretrievably commit resources to future projects. Therefore none of the past, present or reasonably foreseeable future landside projects are functionally "similar" or "connected" with the Airside Project.

In accordance with the FAA directives, as the lead federal agency under NEPA, this Airside Project Supplemental Draft EIS addresses the question of whether the environmental effects of the proposed Airside Project will cause cumulative environmental impacts when added incrementally to the environmental effects of past, present and reasonably foreseeable future actions at Logan.

In addition, this chapter provides an analysis of short-term cumulative impacts from construction activities associated with the Preferred Alternative. This cumulative impact analysis is conducted within the context of short-term construction impacts associated with other projects that are anticipated to be in the construction stage at the same time the construction program for the Preferred Alternative is underway as specified in the May 7, 1999 EOEA Certificate. See Section 7.5 for a discussion of cumulative construction impacts. Section 7.5.1.1 includes a refinement of the truck traffic projected in the Airside Project Draft EIS/EIR from both the Preferred Alternative and other concurrent on-airport projects.

7.2 Relationship to the GEIR/ESPR

The Logan Airport 1994/95 Generic Environmental Impact Report (GEIR*)* and its *1996*, *1997* and *1998 Annual Update*s, EOEA # 3247/5146, (collectively the GEIR) and the subsequent *1999 Environmental Status and Planning Report* (ESPR), EOEA # 3247, provide a comprehensive evaluation of the cumulative effects of growth and change at Logan and serve as a planning tool for current and future projects proposed by Massport. The GEIR/ESPR provides an overview of the relationship of airport operations, as a whole, to local and regional noise, ground access, air quality, and water quality conditions. Individual projects such as the Airside Improvements Planning Project, are described in the GEIR/ESPR. These projects subsequently undergo individual project review under NEPA and/or MEPA if environmental review thresholds are met.

This Supplemental DEIS/FEIR provides in-depth analysis of Logan's future airfield operating conditions with and without the Preferred Alternative. This Supplemental DEIS/FEIR builds upon the Airside Project Draft EIS/EIR and the GEIR/ESPR in its analysis of impacts, and provides a broader understanding of the potential benefits and impacts of proposed changes to existing and future Logan airside operations.

The analysis conditions presented in the GEIR/ESPR are consistent with those used for the Supplemental DEIS/FEIR. Both documents evaluate future conditions at Logan associated with annual passenger levels of 29 million and 37.5 million. The GEIR/ESPR evaluated

impacts for future analysis conditions and all passenger levels using a mid-range aircraft fleet. The *1999 ESPR* evaluated a high "Regional Jet" fleet (High RJ Fleet) for the 37.5 million annual passenger activity level. To more fully identify the range of potential impacts associated with future airfield operations, this Airside Project Supplemental DEIS/FEIR expanded the GEIR/ESPR airport operational analysis by evaluating both a High and Low range Fleet that bracketed the GEIR/ESPR mid-range fleet assumptions. In addition, this Supplemental DEIS/FEIR also evaluates the 37.5 million annual air passenger fleet with a high proportion of regional jets (High RJ Fleet). These fleets represent a range of operational scenarios, reflecting higher and lower numbers of aircraft operations and fleet mixes to deliver the same specific passenger level. In this manner, the impacts of Airside Project proposed improvements are identified as a function of aircraft operations.

This Airside Project Supplemental DEIS/FEIR provides a comprehensive analysis of cumulative impacts associated with the Preferred Alternative. It involves a review of impacts generated by airfield operations (i.e., aircraft takeoffs and landings and taxiing) for 1993 Historic Modeled Conditions, 1998 Actual Conditions and future scenarios of 29 million annual air passengers with a Low Fleet assumption (29M Low Fleet), and 37.5 million air passengers with an RJ Fleet as well as the High Fleet (37.5M High Fleet). The impact analysis applicable to future years is based on passenger forecasts and fleet forecasts and employs detailed modeling. (See discussion at Chapter 4.0 for assumptions and other details of these forecasts and modeling techniques.) The *1994/95 GEIR* provided a similar review of comprehensive impacts for such operations, based on identical passenger forecasts and similar modeling techniques.

As discussed in more detail in the following sections, this Airside Project Supplemental DEIS/FEIR supplements the analysis of impacts from airside operations that was provided in the *Logan Airport 1994/95 GEIR* and the *1996, 1997, and 1998 Annual Updates* and the *1999 ESPR* by including the following:

- Analysis of high and low aircraft fleets scenario, compared to analysis of mid-range fleet in the GEIR;
- New cumulative noise impact analysis which takes into account changes in runway utilization that result from some of the improvements under review and a greater ability to achieve PRAS goals; and
- New cumulative air quality impact analysis based on changes in aircraft taxiing routes and patterns that are intended to result from certain of the improvements under review.

It should be noted that the GEIR/ESPR air quality comprehensive impact analysis is based on two component categories of operation, landside and airside. The air quality analysis provided in this Airside Supplemental DEIS/FEIR supplements the GEIR/ESPR analysis only to the extent that it incorporates changes associated with the proposed Airside Project improvements. Airside Project improvements under review do not relate to or affect any of the landside facilities or operations, and consequently, do not change any of the air quality impact analysis of landside facilities or operations presented in the GEIR/ESPR.

Overall, this Airside Supplemental DEIS/FEIR complements the findings of the GEIR/ESPR and provides an analysis of the potential cumulative impacts and benefits of the airside and landside projects. The assessment of the environmental effects of airport operations described in the *1994/95 GEIR* and the *1996, 1997, and 1998 Annual Updates* and the *1999 ESPR* are incorporated by reference in this Supplemental DEIS/FEIR and provide a starting point for the environmental impact analysis presented in this Supplemental DEIS/FEIR.

7.3 Relationship of the Logan Airside Improvements Planning Project To Other Logan Projects

The purpose of the Airside Improvements Planning Project is to reduce current and projected levels of airfield congestion and delay and to enhance the safety of aircraft operations at Logan. Massport's proposed landside improvements are planned to enhance the efficiency of passenger processing, and include terminal modernization, as well as roadway, parking and service area improvement**s**. The landside projects will not affect the design or implementation of the Airside Project, which has independent utility, nor will the Airside Project improvements affect the design or implementation of any of the landside projects.

All other airside and landside projects, where required, will continue to be the subject of separate comprehensive environmental analysis by project proponents in accordance with federal and state regulations.

A summary of other Massport projects follows (See Figure 7.3-1 for the project location.). For additional information, please refer to the *Logan Airport 1998 Annual Update*[3] and the *1999 ESPR*.[4]

7.3.1 Logan Modernization Projects

Logan Modernization is a Massport capital investment program currently underway to address current and future passenger activities and facilities. Logan Modernization consists of projects that will modernize the terminal areas and other landside facilities to address problems of terminal overcrowding, roadway congestion and inadequate parking. Implementation of Massport's proposed terminal projects as described below will enable Logan to provide modern, efficient service to its passengers.

Foreseeable Projects: Airside and Landside

7.3.1.1 West Garage Project, Elevated Walkways and Terminal Roadways

In March 1995, the West Garage Project Final EIR/EA was determined by the Secretary of Environmental Affairs to adequately comply with MEPA. The FAA issued a Finding of No Significant Impact (FONSI). This FONSI considered the impact of past, present, and foreseeable projects.

Phase I of the West Garage Project opened in September 1998. This project consolidated 3,150 parking spaces from remote, at-grade parking lots serving Logan Airport, and offset the loss of spaces to other Logan Airport landside construction projects.

With the West Garage addition in the terminal area parking complex, Logan Airport created a convenient Central Parking Facility to serve the terminal area. Elevated pedestrian walkways link the facility to the four terminals. Walkways with moving sidewalks connect the West Garage to Terminals A and E, including walkways with floor mosaics, which became the largest public art installation in New England. In 1999, the construction of the walkways to Terminals B and C began, with expected completion in 2001. Public art features will also be featured on these walkways.

Massport has evaluated design options for Phase II of the West Garage and has concluded that the most cost effective way to proceed with Phase II is to add three levels of parking to the Central Garage rather than provide the spaces in the location originally planned. A Notice of Project Change (NPC) was filed with the Executive Office of Environmental Affairs, Massachusetts Environmental Policy Act (MEPA) Office on October 31, 2000 describing the proposed changes and associated environmental impacts. The Secretary's Certificate on the NPC, issued December 8, 2000, indicated that no further MEPA review is required.

Terminal roadway improvements will be coordinated with the CA/T and Logan Modernization projects to incorporate the airport roadway system into the regional highway system and to improve vehicle capacity and access to the terminals. The roadway improvements have been designed. Construction has commenced and is expected to be completed in 2002.

7.3.1.2 International Gateway/Federal Inspection Services

The International Gateway Project is being built in response to the continued growth in international activity by both US and foreign flag carriers at Logan Airport. As New England's principal international gateway, Logan Airport and Terminal E are critical links for the City's and region's economy to an increasingly global marketplace. A state-of-the-art, high-efficiency facility will enlarge Logan Airport's congested Federal Inspection Services (FIS) facility, the meeter/greeter lobby, and the ticketing area, and ultimately maximize passenger convenience and reduce processing times. The FIS facility will be located south of the existing Terminal E. Additionally, to reduce curb and roadway congestion at the terminal, this project also includes a new double-decked roadway system for arrivals and departures.

The Final EIR/EA for the International Gateway Project was determined to adequately comply with MEPA in December 1996. The FAA issued a FONSI under NEPA. This FONSI considered the impact of past, present, and foreseeable projects.

Construction of Phase I of the International Gateway Project began in 1998, with an anticipated completion in 2003. Phase II, a new West Concourse, which will add three gates to handle international activity, is anticipated to commence sometime after 2003.

The Central Cooling and Heating plant is being rehabilitated to support both the existing facility requirements and the Logan Airport Modernization projects. These heating and cooling upgrades will be constructed in phases. The project will support the new FIS facilities and include the replacement of cooling towers and other facilities to provide adequate service, airport wide. Construction began in 1998 and is expected to be completed in 2001.

7.3.1.3 Airport Intermodal Transit Connector

The Airport Intermodal Transit Connector (AITC) project is part of an interagency effort undertaken by Massport and the MBTA. The proposed AITC will provide a user-friendly transit alternative for air passengers and other users of Logan Airport such as employees and meeters/greeters. The AITC will be a "dual-route," enhanced bus service that will directly connect Logan Airport with South Station (the red route) via the Ted Williams Tunnel and the South Boston Transitway, and with the MBTA Blue Line (the blue route).

The two-route AITC bus system will expand the intermodal reach of Logan Airport. It will represent a new public transportation route between Logan Airport and South Station, and will improve intermodal links between Logan Airport and the MBTA Red Line, the commuter rail, and the intercity rail (Amtrak). The new Airport Station will provide an improved connection to the AITC Blue line; it also may become a stop on the MBTA's proposed Circumferential Transit service. The AITC will create an alternative option for a one-seat ride from both the Financial District and the South Boston Seaport District to the Logan Airport terminals.

Both routes of the AITC are expected to be fully operational by 2003 with timing dependent upon completion of the MBTA's South Boston Piers Transitway Project and the new MBTA Blue Line Airport Station. The AITC is currently on the Massachusetts Transportation Improvement Program (TIP), making it eligible for Federal funding. Massport is working with the MBTA to procure new buses for the AITC and to address other issues regarding operations, maintenance, scheduling, and program requirements.

Logan DART

In the interim until the AITC is operational, a new Massport sponsored shuttle service began operation on November 15, 2000. The service is named the Logan DART and operates Sunday through Friday from 6 AM to 8 PM. There are two stops at South Station; at Gate 25 and outside

on Summer Street. The service uses the Ted Williams Tunnel to travel between South Station and Logan Airport, with buses leaving every 15 minutes. The vehicle stops at all terminals at Logan Airport. The fare is $5 each way with discounted fares for Logan Airport employees and Logan Employee Transportation Management Association (TMA) members.

7.3.1.4 Terminal A Replacement

Massport is currently working with Delta Air Lines to implement the replacement of Terminal A with a contemporary terminal facility. The replacement terminal is designed to enable Delta Air Lines to process current and forecasted passenger throughput with a high degree of passenger amenity, safety, and efficiency. The facility consists of a main terminal located on the airport roadway with ticket and baggage services. This is linked via a pedestrian tunnel to a satellite concourse located along Harborside Drive. The satellite concourse has been designed to serve as a noise buffer between Logan Airport and the adjacent Jeffries Point neighborhood. The project design incorporates sustainable design and construction principles to minimize overall impact on the human and natural environment.

On December 8, 1999, an Environmental Notification Form (ENF) that describes the Terminal A Replacement Project was filed with MEPA. On January 7, 2000, the Secretary of Environmental Affairs issued a scope for the preparation of a Draft Environmental Impact Report (EIR). On May 31, 2000, a Draft EIR/Environmental Assessment (EA) was filed with MEPA and the Federal Aviation Administration (FAA). FAA issued a FONSI on September 13, 2000. This FONSI considered the impact of past, present, and foreseeable projects. A Final EIR was filed with MEPA on October 2, 2000, and on November 16, 2000 the EOEA Secretary approved the project with a finding that the Final EIR was adequate. No further environmental review is required.

7.3.1.5 Jet Fuel Storage Facility

A replacement Jet Fuel Storage Facility for the five existing, separately owned and operated facilities in the North Cargo Area was completed in October 1999. The new storage facility is now consolidated and upgraded from the former system and is managed by one entity. On-airport storage capacity is increased to support the types and numbers of planes expected to use Logan Airport. Consolidation allows Massport to strengthen environmental controls such as leak detection and spill containment and to improve safety equipment and management.

The Secretary of Environmental Affairs determined that the Final EIR for the jet fuel facility adequately complies with MEPA in May 1996. No further environmental review was required. The FAA determined the project to be categorically excluded under NEPA.

7.3.1.6 Jet Fuel Distribution System

A new underground Jet Fuel Distribution System around the airport's terminal areas also was completed in October 1999. The new system includes connections between existing and new individual terminal hydrant systems and an emergency fuel shut-off. The system

supplies jet fuel by a hydrant system to most aircraft gates. The Jet Fuel Distribution System has been designed and constructed to meet future fueling needs in accordance with industry engineering and environmental standards.

An ENF was filed with MEPA in January 1994. Notices of Project Change were filed in June 1995 and February 1996 which required no further review. The FAA determined the project to be categorically excluded under NEPA.

7.3.2 Other Terminal Area Improvement Projects

In addition to the Logan Modernization projects, Massport also planned or is anticipating a range of landside projects that will improve airport service areas, tenant facilities and airport maintenance programs, as described below.

7.3.2.1 Replacement Hilton Hotel

Groundbreaking for the Hilton Hotel took place in December 1997, and the hotel opened in Fall 1999. The site for the hotel is located on an 8.1-acre parcel in the central terminal area of Logan Airport, adjacent to the West Garage. The existing Ramada Hotel was demolished in 2000 to make way for the improved Main Airport Roadway.

Following the submission of an ENF in May 1996, the Massachusetts Executive Office of Environmental Affairs (EOEA) issued a decision in July 1996 granting a waiver from the preparation of an EIR. The FAA determined that the project was categorically excluded from the requirement for formal Environmental Assessment. In April 1997, the project proponent filed a Notice of Project Change to reflect a reduced building height and slightly increased building size. In May 1997, EOEA issued a Certificate requiring no further environmental review. The project was not subject to NEPA.

7.3.2.2 US Airways Terminal B Consolidation

As described in the *1997 and 1998 Annual Update*, US Airways is consolidating its mainline, Metro Jet, commuter, and Shuttle (formerly at Terminal A) operations in one location. To accommodate these operations, Terminal B's Pier B was modified. This project included the construction of a two-level addition totaling 65,000 square feet at the south end of Terminal B, Pier B, providing additional holdrooms, concession areas, baggage handling, and airside operations space. These improvements will allow US Airways to operate more efficiently and will improve passenger service. Construction of the US Airways Terminal B Consolidation Project began in 1999 and is expected to be completed by 2002. The FAA determined the project to be categorically excluded under NEPA.

7.3.2.3 United Airlines Terminal C, Pier B Improvements

United Airlines is consolidating its services and facilities from different terminals to Terminal C, Pier B. An ENF was submitted to the Secretary of Environmental Affairs in April 1998 and a Certificate requiring no Environmental Impact Report was issued in May

1998. The FAA determined the project to be categorically excluded under NEPA. Construction of the project began in early 1999 and will be completed in 2001.

7.3.2.4 American Airlines Terminal B, Pier A Improvements/ Massport Satellite FIS Facility

Massport and American Airlines are proceeding with improvements to Terminal B, Pier A, to better accommodate current passenger demands and anticipated future passenger growth. American Airlines proposes to consolidate all of its Boston operations, including its existing domestic and international operations, into one location. American plans to do this by renovating the existing Pier A of Terminal B to provide improved circulation, ticket space, baggage handling, concessions, and other amenities. To accommodate more efficiently the growing international market, Massport proposes to construct a new satellite FIS facility at the southeast end of Terminal B, Pier A.

On May 31, 2000, a joint Massport / American Airlines ENF was filed with MEPA. On June 7, 2000, the Secretary of Environmental Affairs issued a Certificate on the ENF requiring an EIR. On August 24, 2000, the FAA determined the projects to be categorically excluded under NEPA. The projects meet the General Conformity requirements of the Clean Air Act, as amended.[5] Massport and American Airlines are now proceeding with the preparation of a Draft EIR for these projects.

7.3.3 Other Service Area Projects

Massport is engaged in on-going strategic planning to explore ideas for more efficient use of limited land resources within the airport service areas. The four airport service areas at Logan are the North Service Area / North Cargo Area, Southwest Service Area, Bird Island Flats / South Cargo Area, and Governors Island. Service area activities include but are not limited to the following: freight / air cargo operations, aircraft maintenance, food preparation, and airfield and facilities maintenance. Table 7.3-1 provides a brief description of projects and planning concepts in the service areas, both Massport-sponsored and tenant-sponsored, that have evolved since the submission of the *Logan Airport 1998 Annual Update* and *the Airside Improvements Planning Project Draft EIR/EIS*. More detailed project descriptions follow.

7.3.3.1 ParkEx Relocation

According to a 1991 Memorandum of Understanding between Massport, MassHighway, the City of Boston, and Bremen Street Trust (owners of the ParkEX parking facility), the 1,377-space ParkEX facility was to be moved from its current 12-acre, off-airport location on Bremen Street to an 11-acre site that is currently used for rental car parking in the Southwest Service Area (SWSA) of Logan Airport.

The East Boston Three-Way Land Transfer ENF and EIR that were submitted to MEPA in Spring and Fall 2000, included a description of the relocation of ParkEX facility to the

5 Letter from John Silva, Manager, Environmental Programs, Federal Aviation Administration, New England Region, to Ken Hietbrink, American Airlines, and Betty Desrosiers, Massport. Dated August 24, 2000.

Table 7.3-1
Status of Airport Service Areas Projects and Planning Concepts

Massport Projects and Planning Concepts	**Status of Planning, Design and Construction[1]**
North Service Area/North Cargo Area – Uses include aircraft parking, cargo facilities, hangars, ground service equipment (GSE), employee parking, flight kitchens, construction staging and navigational equipment.	
Jet Fuel Storage Facility A replacement storage facility to consolidate, upgrade and increase capacity of the existing fuel farms.	Complete.
Jet Fuel Distribution System A new underground system to deliver jet fuel directly to most aircraft gates will meet future fueling needs in accordance with engineering and environmental standards.	Complete.
Replacement Cargo Buildings Replacement of aging and undersized cargo buildings, and of cargo facilities demolished due to CA/T roadway work will be required.	This concept is in the preliminary planning stages.
Replacement Hangar Facilities Replacement hangar facilities due to CA/T roadway work will be required.	This concept is in the preliminary planning stages.
Southwest Service Area – Serves as the airport ground transportation hub (car rental, taxi/bus/limousine pool, commercial parking).	
Consolidated Rental Car Facility Consolidated, structured rental car facility is being considered.	This concept is in the preliminary planning stages.
ParkEx-Transaction (formerly Park 'N Fly) Buy-Out Alternative.	Land Transfer Project underway.
Bird Island Flats/South Cargo Area – Uses include replacement cargo facilities, parking, and potential commercial development.	
Cargo Building 63 Cargo building located along Harborside Drive over a portion of the Ted Williams Tunnel.	Complete.
Water Shuttle Dock Improvements Dock to be expanded to accommodate the demand of additional vessels and to comply with handicapped accessibility requirements.	Construction will begin in summer 2001.
Tenant Improvement Projects	
United Airlines Ground Service Equipment Building Existing facility being demolished to make way for CA/T roadway work. Construction began on the new 17,000 square foot GSE facility in the North Cargo Area adjacent to the United Hangar in 1998.	Complete.
US Postal Service Facility Relocated USPS facility to meet future shipping needs. A new location has not yet been identified.	This concept is in the preliminary planning stages.

1 Status as of Winter 2001

SWSA, along with its environmental impact assessment. After the filing of the ENF and EIR, Massport, ParkEX, and the CA/T Project concluded that an alternative land transfer ("Buy Out Alternative") offered important environmental and operational advantages. The Buy Out Alternative involves the purchase of the Bremen Street lot by Massport, the transfer of this parcel to MassHighway to allow for the construction of a park, and the transfer of the Robie Industrial Parcel to Massport. No transfer of existing airport land is involved. The 1,377 parking spaces from the Bremen Street lot will be transferred to Logan Airport. The Buy Out Alternative better facilitates CA/T Project construction of the Route 1A interchange highway improvements than under the approved East Boston Three-Way Land Transfer. A Notice of Project Change (NPC) describing the Buyout Alternative was filed with MEPA on October 31, 2000 and EOEA determined that no further environmental review was required. Transfer of the Bremen Street lot and the Robie Industrial Parcel pursuant to the Buy Out Alternative was completed in January, 2001.

7.3.3.2 Robie Industrial Parcel

The Robie Industrial parcel, owned by Massport, is located adjacent to the North Cargo Area of the airport. The 6.9 acre parcel, a former airport industrial park, is currently used for airport parking and as a construction staging area for CA/T project construction. A replacement cargo building is proposed on the parcel.

7.3.3.3 Replacement Cargo Buildings

The demolition of air cargo buildings 12 and 13 to accommodate the CA/T roadways will sharply reduce Logan Airport's air cargo space in the North Cargo Area. In the North Cargo Area alone, more than 150,000 square feet of cargo building space is being demolished to accommodate the CA/T roadways. Replacement on-airport cargo facilities are needed in order to meet existing needs of the air cargo industry operating at Logan Airport.

7.3.3.4 Consolidated Car Rental Facility

Massport is evaluating the feasibility of consolidating rental car operations in the SWSA to accommodate all car rental operations. Storage and maintenance of portions of the rental car company fleets are currently dispersed throughout the service areas and at off-airport locations. A consolidated car rental facility would reduce the number of on-airport, shuttle bus trips that currently run between the individual car rental lots and the terminals. Rental car consolidation is a growing national trend at major commercial airports for its land use conservation, and reduced roadway impacts.

7.3.3.5 Water Shuttle Dock Improvements

Massport will be expanding the existing on-airport water shuttle dock to accommodate the growing demand for additional vessels and to comply with handicapped accessibility requirements. The project is not subject to MEPA or FAA NEPA review. Construction is anticipated to begin in 2001.

7.3.4 Tenant Improvements

Massport leases airport land and building space to a variety of public and private tenants who require proximity to the airport. Government offices include the Immigration and Naturalization Service (INS), the Department of Agriculture, and the FAA. Private tenants include cargo companies, flight kitchens, car rental agencies, and airlines. These tenants have the right to occupy, use and improve their leased areas, subject to and in accordance with their lease terms and all relevant federal and state regulations.

Tenant improvement activities involve a variety of projects including minor leasehold improvements such as non-structural alterations and minor cosmetic work, equipment installation, building additions and tenant relocations, as well as major capital investments by airlines to improve terminal facilities.

The majority of the tenant improvement projects are generally limited to renovation, repair, furnishing, or equipping existing building space. Tenant projects that are of a scope or character that meet any MEPA or NEPA threshold for environmental review proceed through the appropriate environmental review process.

Major tenant projects currently being evaluated, planned, or constructed in the service areas include the United Airlines Ground Service Equipment Building, replacement hangar facilities, and the USPS facility. Below are brief descriptions of each.

7.3.4.1 United Airlines Ground Service Equipment Building

The existing United Airlines ground service equipment (GSE) building was demolished for the CA/T project. Construction began in the fall of 1998 on a 17,000 square foot replacement facility in the North Cargo Area adjacent to the existing United Airlines Hangar. The building was completed and operational in late 1999.

7.3.4.2 United States Postal Service Facility

The United States Postal Service (USPS) Logan Airport Mail Center in the South Cargo Area provides the USPS with direct airside access to air transportation carriers. However, this facility is inadequate to accommodate future USPS shipping needs and must be replaced with a new facility that can provide continued, secure airside access. Although the USPS does not own or operate a fleet of aircraft, it does lease aircraft to accommodate both airmail and express package shipments. In addition, all major US carriers under contract with the USPS provide belly capacity to carry US mail under contract with the USPS. The major carriers provide both aircraft capacity and line-haul transportation. The line-haul function is on the apron where the airlines "tugs" mail to/from their aircraft to the air mail facility. The line-haul/tug operation therefore requires secure airside access. The North Cargo Area/North Service Area is one location under consideration for the replacement facility.

7.3.5 Airport Edge Buffer Projects

Massport's goal is to enhance the public edges of Logan Airport with attractive architecture and landscape improvements. Massport has committed up to $15 million to the planning, future construction, and maintenance of the Logan Airport Edge Buffers. These buffers include properties located in various areas generally along Logan Airport's perimeter boundary. (See Table 7.3-2).

The buffers will be designed in consultation with Logan Airport's neighbors and others through an open community planning process. To discuss East Boston open space planning, Massport also participates in meetings with other state and city agencies including MassHighway, the CA/T Project, the MBTA, the City of Boston's Environment Department, and the Boston Redevelopment Authority. The project is not subject to NEPA.

Table 7.3-2
Edge Buffer Projects

Edge Buffer	Status
Bayswater Embankment Buffer	In early 1998 through the Spring of 2000, Massport began a community planning process to develop a landscape beautification and streetscape improvement program for the Bayswater Embankment. In July 2000, construction began with expected completion in 2001.
Navy Fuel Pier Buffer	Massport is helping the Jeffries Point neighborhood facilitate the Army Corps of Engineers' (ACOE) remediation of this site, the former Navy Fuel Pier. The Jeffries Point Neighborhood Association is regularly briefed on the project's progress. ACOE expects to announce an appropriate remediation plan for the contaminated soil by Spring 2001. The schedule and scope of any remediation plan will help Massport and the neighbors develop an appropriate design and construction schedule. Massport intends to initiate a landscape design consultant selection process in early 2001.
SWSA Buffer	In the Spring of 1999, Massport selected a consultant team to lead the design process for the SWSA landscape buffer. Design of the SWSA buffer will be timed to coincide with other development in the SWSA (i.e. relocation of ParkEX). Massport described the SWSA Buffer and presented preliminary concept plans in the East Boston Three-Way Land Transfer ENF and EIR filing. In 2001, Massport has started a community planning process to design the SWSA Edge Buffer concurrent with the site's future development.
North Service Area Buffer	In January 1997, Massport selected a landscape architect/planning firm to lead the design process for the NSA Buffer. The team developed schematic designs with input from the neighbors. Due to neighborhood members' concerns over the possibility of increased public access near their homes, this project, at the request of the neighborhood, was put on temporary hold until further notice.

7.3.6 Other Airfield/Airside Improvement Projects

7.3.6.1 Blast Fence Removal

Recent accidents involving blast fences at airports across the US have highlighted the need to remove airfield barriers and raised awareness of this nationwide safety problem. The National Transportation Safety Board (NTSB), in a September 19, 2000 letter to Massport,

stated that the Blast Fence at the end of Runway 22R "constitutes a safety hazard and should be removed." In response, Massport has proposed the removal of the Blast Fence that was originally constructed in 1976. Subsequent to construction of the fence, the FAA developed safety regulations and policies that designate specific surfaces and areas around runways that must be maintained free of obstructions to maximize aviation safety. A detailed analysis of the Blast Fence found that it penetrates seven of nine applicable FAA safety surfaces and areas.

On November 30, 2000, Massport voluntarily filed an ENF to facilitate review by the adjacent communities and environmental agencies prior to removal of the fence. In February 2001, EOEA determined that no further environmental review was required. It is expected that the fence will be unbolted from its footings in sections and the dismantled wood pieces will be immediately removed from the airfield.

7.3.6.3 Runway 33L Safety End Improvements

The project involves constructing a safety area at the end of Runway 33L to accommodate aircraft overruns or overshoots in an emergency situation. Preliminary options are being discussed and evaluated with the FAA. Environmental documents will be filed once project concepts and alternatives are better defined. Since the project alternative analysis is not yet complete, the project is not reasonably foreseeable.

7.3.7 Other Major Projects

In addition to the Massport and tenant-related projects previously described, the following major projects will also occur on the airport, and are considered in the evaluation of cumulative impacts.

7.3.7.1 CA/T Project

The CA/T Project will link the Massachusetts Turnpike (I-90) to Logan by way of a four-lane tunnel beneath Boston Harbor. The Ted Williams Tunnel is complete and was opened to traffic in December 1995. In addition to the tunnel, the following three CA/T Project components involve construction on the airport:

- Contract C07D2, involving connections of the Ted Williams Tunnel to the main airport circulation roadway system that is now substantially complete;
- Contract C08A1, involving connections of the main airport circulation roadway system to Route 1A, and;
- Contract C07C1, involving construction of toll facilities.

Massport has worked closely with the MassHighway and the Massachusetts Turnpike Authority (MTA) to coordinate airport activities during the implementation of the CA/T Project in order to ensure efficient and uninterrupted operations. Construction of the airport-related components of the CA/T Project is estimated to be completed in 2002. The

CA/T Project has completed its own extensive MEPA/NEPA environmental review with the issuance of a Certificate and a Record of Decision (ROD).

7.3.7.2 Massachusetts Bay Transportation Authority (MBTA) Blue Line Modernization Program

The MBTA Blue Line Modernization Program includes improved station safety, cleanliness, lighting, barrier-free access to all Blue Line stations and lengthening of station platforms to accommodate six-car trains.

The MBTA is developing a new Logan Airport Station to be located about 400 feet north of the existing Logan Airport Station. Massport is consulting with the MBTA on the project's design and operational elements. The new Logan Airport Station will include modern passenger amenities such as wide escalators, oversized elevators, and real-time flight information displays in the station lobby. It will also provide a convenient at-grade connection to the neighborhood, AITC Blue Route and Logan Airport, and may become a stop on the MBTA's proposed Circumferential Transit (Urban Ring) service. There is no Federal FAA jurisdiction over this action.

7.3.8 Other Projects In East Boston

Other off-airport projects are expected to occur in East Boston in the foreseeable future as described below. These projects are still in the early stages of planning and design. They have not been subject to detailed quantitative and cumulative construction period impact analyses and no specific construction period has been established. While these projects might overlap in time with the construction of the Airside Project Improvements, they do not overlap geographically with the airside construction. Mitigation measures employed for the Airside Project are designed to avoid or minimize construction impacts off the airport and therefore, no cumulative construction impacts are anticipated as a result of these other East Boston projects.

7.3.8.1 Maverick Station

MBTA is updating the Maverick Station as part of the Blue Line Modernization program. The project is currently in preliminary design with construction anticipated in 2004.

7.3.8.2 Redevelopment of Massport Piers 1 and 5 and the Massport Shipyard

Redevelopment of Massport's Piers 1 and 5 and shipyard are still in the early planning phases. The plan for redevelopment of Pier 1 anticipates residential development, while Pier 5 is expected to be an expansion parcel for the adjacent marina. It is anticipated that the shipyard will be repositioned to decrease its impact on the adjacent community. Planning is in the preliminary concept stages.

7.4 Long-term Cumulative Effects

This section discusses the long-term cumulative effects of the proposed airside alternatives in the context of aircraft operations, and therefore focuses on a discussion of noise and air quality impacts. Other impacted resources discussed in the previous chapters, such as biotic communities, water quality and soils are associated only with this project and are limited to the confines of the airfield. Because these impacts are geographically isolated from other projects, they do not contribute to long-term cumulative impacts. The proposed Airside Project is consistent with local land use plans and will not result in the division or disruption of established communities, since all construction would occur on the airport.

The mitigation measures proposed for the Airside Project improvements minimize long-term adverse impacts. Therefore no long-term adverse cumulative impacts result from the implementation of the Airside Project improvements identified within the context of the Airside Project. Temporary construction impacts do result from the project and the potential for cumulative construction impacts has been considered. A discussion of the short-term cumulative impacts associated with the construction of the Airside Project improvements and other past, present, and reasonably foreseeable projects is presented in Section 7.5.

7.4.1 Noise

Ambient noise levels at Logan are dominated by noise from aircraft operations. A review of the environmental documentation for the Logan Modernization and CA/T projects was conducted to assess the potential for cumulative noise impacts.

The noise analysis conducted for the International Gateway evaluated impacts that might result from a change in the spatial arrangements for aircraft/vehicle operations at Terminal E. This analysis found that there are no impacts due to aircraft in-flight noise, since the project does not affect the projected volumes of air passengers, and thus, the number of flights (landings and takeoffs) at Logan. There were also no impacts due to ground noise at any of the community receptor sites analyzed in any year or scenario as a result of the International Gateway. When compared to the No-Build Alternative, the International Gateway would result in differences in noise levels of less than 0.7 decibels (dB) at all of the community sites for the 2010 future analysis. The FAA considers increases in day-night average sound level (DNL) over noise sensitive land uses of 1.5 A-weighted decibels (dBA) or greater to be the threshold of significant noise impacts in areas above 65 dBA, measured in DNL.

The cumulative noise analysis conducted for the Terminal A Replacement Project also determined that there were no significant noise impacts associated with improvements at Terminal A. [6]

6 Terminal A Replacement Project, Federal Environmental Assessment, May 31, 2000.

Noise analysis conducted for the CA/T Project in the East Boston/Logan Airport area found no impact based on the Federal Highway Administration (FHWA) noise criteria at 12 of the 13 receptor sites evaluated. A minor noise impact from the CA/T Project at the East Boston Memorial Stadium Park was identified in the CA/T Project Final Supplemental Environmental Impact Report (FSEIR).[7] The current design of the project in this area however, does not require mitigation.

Given the fact that there are only minor impacts in discrete areas associated with any of the other concurrent projects at Logan, there are no material cumulative noise impacts created by the combination of these projects with the proposed Airside Project improvements.

Aircraft operations are the determining factor in evaluating noise impacts associated with airport operations. By examining the effect of all aircraft operations, including in-flight as well as ground taxiing noise, the assessment of noise impacts conducted for the Airside Project is cumulative in its approach. Cumulative noise metrics used in the Airside Project Draft EIS/EIR analysis included DNL and Time Above (TA) specified threshold sound levels. DNL noise exposure contours are a graphical representation of how cumulative noise from Logan's aircraft operations is distributed over the surrounding area on an average day of a given year.

Implementation of the Preferred Alternative (Alternative 1A) was shown to reduce delay and provide Air Traffic Control (ATC) with a greater ability to meet the Preferential Runway Advisory System (PRAS) goals. The Preferred Alternatives also reduce ground noise by reducing taxiing queues. The results of the noise impact assessment indicate that for all future fleets and scenarios, the Preferred Alternative provides a significant reduction in the most severely affected populations in East Boston, Winthrop and Revere that are within the 70 and 75 dB noise contours. They result in a slightly larger population within the 65 dB DNL in Chelsea due to a greater use of Runway 33L in accordance with PRAS goals. This impact will be mitigated by sound insulating affected residences within the 65 dB contour. (See Section 6.2 for a detailed discussion of noise assessment results.)

7.4.2 Air Quality

The air quality assessment conducted for the Airside Project addressed the cumulative impacts associated with all airport-related sources of air emissions at Logan, including aircraft, ground service vehicles, fuel facilities, and on-and off-airport motor vehicles. The same passenger levels developed in support of the *1994/1995 GEIR*, the *1996, 1997* and *1998 Annual Updates*, and the *1999 Environmental Status and Planning Report*, air quality analyses (29 million passengers in 1999 and 37.5 million passengers in 2010 (2015)) formed the basis for the Airside Project assessment.[8] Similarly, on- and off-airport motor vehicle traffic data were the same for both studies. In this way, the air quality impacts associated with the

▼

7 *Final Supplemental Environmental Impact Report (FSEIR)*, Massachusetts Department of Public Works, November 1990.

8 Massport has reviewed its previous planning forecasts, and regional and national aviation developments, and has adopted a new long-term forecast for when annual air passengers are expected to reach 37.5 million, now anticipated to be the 2015-planning horizon. The *1999 ESPR* and subsequent EDRs no longer evaluate the 2010 analysis year but will analyze the environmental effects of Logan Airport accommodating 37.5 million annual air passengers. All evaluations are based on passenger levels and therefore cumulative assessments remain consistent.

Airside Project alternatives were evaluated as part of the long-range development plan for Logan, and were not assessed independently as a separate component. This approach therefore assessed cumulative air quality and odor impacts associated with all landside and airside projects at Logan.

To completely assess cumulative air quality impacts, both emission inventories and dispersion modeling of existing and future year conditions were undertaken (see Sections 5.4 and 6.4 for a detailed discussion of the air quality modeling and assessment). The purpose of this assessment was twofold: (1) to compare the results to regulatory standards or criteria, and (2) to compare the impacts from the Preferred Alternative to the No Action Alternative.

The results of the emission inventories and dispersion modeling indicate that:

- There are no predicted violations of any federal and state standards or guidelines under any future scenarios or alternatives; and

- Due to improved airfield operating efficiency and reduced delay, the overall air quality impacts associated with the Preferred Alternative are beneficial or will remain imperceptible, when compared to the No Action Alternative.

- Air quality emissions associated with motor vehicles are the same for all Airside Project alternatives, including the No Action Alternative.

A comparison of the air quality impacts from the Airside Project to other past, present, and reasonably foreseeable projects is presented in Table 7.4-1. Each of the individual projects (Airside Project, West Garage, International Gateway, Jet Fuel Storage and Distribution Facilities Central Artery, AITC, and Terminal A Replacement), result in air quality improvements or, in the case of the Replacement Hilton Hotel, minor, imperceptible changes in air quality. Therefore, there are no cumulative air quality impacts associated with these projects.

The Terminal B, Pier A / Satellite FIS Facility improvements proposed by American Airlines and Massport are undergoing appropriate MEPA / NEPA review. Because the project itself will not induce change in the number of motor vehicles, aircraft, or support equipment, no additional emissions from these sources will be created as a result of the Terminal B, Pier A / Satellite FIS Facility. Furthermore, because the project will result in greater operating efficiency and less congestion on both the airside and the landside, emissions for the aforesaid mobile sources likely will decrease. In addition, gates will be fitted with provisions for electricity and pre-conditioned air, thereby reducing emissions from aircraft auxiliary power units.

Table 7.4-1
Cumulative Air Quality - Year 2010 (Emissions in kg/day)

	Comparison of Action minus No Action Alternatives Emissions		
	VOC	**NOx**	**CO**
Airside - 2010 45M High[8]	**-234**	**-201**	**-1,307**

Terminal A Replacement[7]	-42	-201	-1,307
Subtotal Other Projects	-86	-591	-7,306

1 Final Environmental Impact Report, *West Garage Project*, Boston-Logan International Airport, January 31, 1996. (Includes Motor Vehicle Emissions only).

2 Final Environmental Impact Report and Environmental Assessment, *International Gateway*, Boston-Logan International Airport, October 15, 1996. (Based on 45 million passenger conditions and includes aircraft, auxiliary power units, and ground service vehicles.)

3 Final Environment Impact Report, *Jet Fuel Storage Facility*, Boston-Logan International Airport, April 16, 1996. (Includes Jet Fuel Storage Facility Emissions only.)

4 Environmental Notification Form, *Replacement Hilton Hotel*, Logan Airport, May 15, 1996. A waiver for the preparation of an Environmental Impact Report was granted by MEPA in July 1996. The Replacement Hilton Hotel will generate approximately 260 more trips per day than the existing hotel. The increase in emissions due to these new trips represents less than one percent of total airport traffic and is not considered an impact.

5 Final Environmental Impact Report, Central Artery (I-93)/Tunnel (I-90) Project, November 1990.

6 Environmental Assessment, Airport Intermodal Transit Connector. Boston-Logan International Airport, January 1998.

7 Terminal A Replacement Project, Federal Environmental Assessment, May 31, 2000.

8 Logan Airside Project Draft EIS/EIR scenario reflects the Preferred Alternative and includes all emission sources. 45M High scenario used to provide a consistent comparison to the International Gateway Project that used a 45M High scenario is the basis for the air quality analysis.

The results of the air quality impact analysis indicate that the total emissions caused by any of the Airside Project alternatives are below all applicable emission levels (under 40 CFR s.93.153 (b)) that would trigger the requirement for a conformity determination. The Airside Project is presumed to conform with Section 176(c) of the Clean Air Act with regards to the State Implementation Plan (SIP). This conclusion was reached because the Preferred Alternative is shown to result in a net reduction in future year emissions when compared to the No Action Alternative condition and therefore conforms to the SIP. This benefit is largely attributable to improved airfield efficiency with the proposed improvements. Atmospheric dispersion modeling conducted in conjunction with this analysis also shows that the proposed Airside Project will not cause, nor contribute to, violations of the National Ambient Air Quality Standard (NAAQS) for carbon monoxide (CO), ozone (O_3) or any other EPA-criteria air pollutant. Because emissions are reduced, the Preferred Alternative produces air quality benefits when compared to the No Action Alternative. There are no air quality impacts associated with the Airside Project, and consequently the project does not result in cumulative air quality impacts.

7.5 Construction Impacts and Coordination with Concurrent Major Projects

The cumulative construction impact analyses presented in this Airside Supplemental DEIS / FEIR considers each project impact added to the same kind of impact from other past, present, and reasonably foreseeable future actions regardless of what agency (federal or non-federal) or person undertakes such other actions. Reasonably foreseeable future projects include other planned and developed activities in the affected area, which overlap in time and space and therefore could produce cumulative impacts.

Construction period impacts are generally temporary and of lesser magnitude than long-term impacts. The cumulative construction impacts are not anticipated to be significant due to mitigation programs that will reduce any construction period impacts. (See Section 6.9 for a discussion of construction mitigation.)

7.5.1 Construction Impacts from the Logan Project Improvements and Other Actions

As previously described in Section 6.9, the Airside Project is expected to result in local area impacts during the construction period, which is expected to begin in the spring of 2003 and extend on a phased basis through the Fall of 2007. As illustrated in Figure 7.5 -1, a number of other projects by Massport and other public and private entities are expected to be under construction concurrently with the Airside Project improvements.

The cumulative construction impact analysis for the Airside Project builds upon a similar analysis conducted for the International Gateway project.[9] It provides a reasonable basis upon which to evaluate the construction impacts of the Airside Project Preferred Alternative together with those of other projects, as summarized in the following sections.

7.5.1.1 Construction Traffic

Construction-related vehicle (trucks and other heavy equipment) trips will occur on Logan roadways during construction of the Airside Project and other major on-going projects. Construction of the Preferred Alternative for the Airside Project is estimated to average about 56 daily round-trip truck trips in a given quarter, with a peak period of 92 daily round-trip truck trips occurring during the 2004 construction season.

The combination of the Airside Project improvements with the other concurrent projects during the 2003 to 2007 construction period will generate daily round trip truck trips of approximately 364 per day during the peak calendar quarter. The peak cumulative construction traffic occurs the first quarter of 2003, mostly as a result of concurrent CA / T construction on the airport. Truck traffic associated with construction drops off significantly after 2004 as CA / T construction on the airport is completed. Table 7.5-1 compares the cumulative truck trips associated with the Airside Project with the construction truck trips of all other major concurrent projects. By 2007, all construction truck traffic is expected to be generated by the Airside Project.

2007 / 1st Quarter	54	---	0
2007 / 2nd Quarter	0	56	56
2007 / 3rd Quarter	0	56	56
2007/ 4th Quarter	0	---	0

Note: Other concurrent on-airport projects include the terminal area roadways, CA/T Project Contract 8A1, International Gateway, West Garage Phase II, Terminal B improvements and replacement of Terminal A. See Figure 7.5-1 for Project Construction Schedule.

7.5.1.2 Construction Workers

Construction of proposed Runway 14/32 and the taxiway improvements under the Airside Project would be similar to highway construction projects and is not labor intensive. As many as 50 to 75 people could be working on the Airside Project construction at any one time. On average, it is estimated that 15 to 20 workers would be on-site during a typical shift. This is not a significant addition to the estimated average of 240 workers expected daily during the concurrent International Gateway, terminal area roadways, and CA/T Project construction. By comparison, an average of 15,000 non-construction employees work at Logan on a daily basis.

While some of the construction workers may come from the nearby communities, the market for construction employees is regional. Prohibition of on-site construction worker parking will mean far fewer vehicle trips. Workers are expected to commute to and from the site by using public transportation or high occupancy vehicles (HOVs) such as shuttles or buses. Under Massport's construction period mitigation program, construction workers commuting will be subject to a contractually-required transportation management plan.

7.5.1.3 Construction Air Quality

An emission inventory of construction-related air emissions has been conducted for the Logan Airside projects and presented in Section 6.9.4.2. The purpose of this inventory is to identify and quantify the sources of emissions and measure their relative impacts. This is done by comparing these emission levels to the appropriate Clean Air Act Section 176(c) *de minimis* levels.

This inventory was developed using the EPA models NONROAD (draft) and MOBILE5a_H, with appropriate input provided by the Massachusetts Department of Environmental Protection (DEP). The following site-specific information was used in this analysis: the type of construction equipment and vehicles, usage factors, vehicle trips and mileage, and construction phasing. National data were used for engine horsepower and loading factors, fuel types, and emission factors. The activity levels (hours per year) and emissions associated with each equipment type are contained in Appendix J.

Standard dust-suppression measures, such as the ongoing application of water spray at all Logan construction sites, will be implemented for the Airside Project as well as all other concurrent Massport construction projects. Given the distance between the project site and other land uses off-airport, these measures should minimize cumulative dust impacts on the surrounding communities. There will be no burning of construction debris at any Logan project site. Similar construction measures are in place for the CA/T Project construction, along with a well-developed mechanism of community consultation to manage CA/T Project impacts.

Additional PM_{10} (particulate matter) emissions may occur during the construction period of the foreseeable actions; however, no violation of the PM_{10} standard is expected, given the low levels experienced historically in the vicinity of Logan. The reported 1998 PM_{10} readings at DEP's Bremen Street (East Boston) monitoring location most likely reflect the considerable ongoing construction in the area by Massport and MassHighway, as well as

new Ted Williams Tunnel traffic. In 1998, the second maximum 24-hour PM_{10} value for this site was 48 $\mu g/m^3$, well below the standard of 150 $\mu g/m^3$. In addition, the monitoring data show a downward trend over the past eight years.[10]

As reported in Section 6.9.4.2 and shown in Table 6.9.4.2-1, emissions associated with airside construction projects are well below the levels of the general conformity regulations. Construction emissions are thus presumed to conform with Section 176(c) of the CAA. In addition, Massport is committed to participating in the Massachusetts Clean Air Construction Initiative[11] that would further reduce emissions below the *de minimis* thresholds by use of catalysts and filters with construction equipment. Therefore the construction air emissions when added to emissions of other past, present and reasonably foreseeable projects are not significant. There are no NAAQS violations.

7.5.1.4 Construction Noise

The cumulative noise impacts of concern during construction are generally those caused by equipment operating on site and truck trips to and from the site.

The cumulative construction noise analysis considered the potential noise impact from the construction of the proposed Airside Project improvements and concurrent construction projects at Logan Airport on the closest noise-sensitive areas to the construction zone. Concurrent projects are expected to include the terminal area roadways, International Gateway, and CA/T contract, C08A1. This analysis built upon the cumulative construction noise analysis presented in the Final EIR/EA for the International Gateway (adjusted to reflect current construction schedules) the Replacement Terminal A Draft EIR,[12] and incorporated the results of the construction noise analysis developed for the Airside Project as presented in Section 6.9.

The location of the community noise receptors for the construction noise analysis for the concurrent projects analyzed in the International Gateway EIR/EA reflect the fact that these projects are located within the terminal area of Logan. Construction noise impacts therefore were computed for three representative locations in Jeffries Point (the Jeffries Point Yacht Club, and residences on Maverick Street and in McCormack Square), the East Boston Memorial Stadium Park and a residence on Coleridge Street in Harborview, all in East Boston. The Airside Project improvements construction noise analysis reflects the fact that construction would occur on the airfield. In addition to locations in Jeffries Point (Jeffries Point Yacht Club and Sumner Street near Lamson) and Harborview (Coleridge Street residence), representative locations considered in the Airside Project construction noise analysis included two in Winthrop (Somerset and Johnson, and Loring Road near Court), two in the Bayswater section of East Boston (East Boston Yacht Club and at Bayswater and Shawsheen Streets), and one in South Boston (Farragut Road at Second). Predictions of average daily equivalent (Leq) cumulative noise levels were made for the three sites that were previously analyzed in the International Gateway EIR/EA, as well as

▼

10 *1997 Air Quality Report*, Commonwealth of Massachusetts, Department of Environmental Protection.
11 The goal of the Clean Air Construction Initiative (CACI) is to reduce the emissions associated with construction equipment.
12 Replacement Terminal A Draft EIR, Delta Airlines, October 15, 2000.

in the Airside Project Draft EIR/EIS. Additional information on construction noise was presented in the Replacement Terminal A EA/Draft EIR. This is presented in Table 7.5-2.

The results of the construction noise analysis indicate that the cumulative construction noise at all three sites is less than the ambient noise level, which is dominated by the noise from aircraft operations. The increase in noise levels over the ambient noise level as a result of the construction of the Airside Project improvements and the other concurrent construction projects ranges from 0 decibels to 2.1 decibels. According to the Federal Highway Administration (FHWA) noise criteria, increases of less than 5 dBA are categorized as "no impact."

The Supplemental DEIS/FEIR analysis shows that the Airside Project, in addition to the other Massport and private development projects, will have no noise impacts cumulatively, using the FHWA criteria. The routing of construction-related traffic onto designated haul routes in non-residential areas, as required by Massport, also addresses concerns about noise from construction truck traffic. This conclusion is supported by the fact that Massport has received no construction noise complaints over the past two years of combined Logan Modernization and CA/T Project construction.

7.5.1.5 Other Construction Issues

Construction excavate will be managed at all Logan construction sites in accordance with the provisions of the Massachusetts Contingency Plan (MCP) (310 CMR 40.0000) if contaminant threshold levels are triggered**.** Depending on the level of contaminants, if any, and its suitability for reuse, excavated soil will either be disposed of or recycled at an approved off-site facility. Soil tracking protocols will be implemented from the point of excavation to the designated disposal area. There will be no borrow pits at any airport construction site.

Massport has developed a dewatering and discharge plan for all airport construction projects that provides for treatment and management of contaminated groundwater associated with dewatering activities, a quality assurance program for all dewatering activities, and for needed regulatory submittals for stormwater discharges during construction. Appropriate controls will be used throughout the construction period to ensure that excavation, staging, and demolition activities do not introduce sediment, contaminated water, or construction debris into the groundwater or storm drain system. Where applicable, a general National Pollution Discharge Elimination System (NPDES) permit for construction activities will be incorporated into the construction plans, specifications, and contract of each Logan project.

Massport will implement its construction period mitigation program as generally described in Section 6.7, and continue to refine, adjust and apply that program during construction of the Airside Project in order to minimize potential noise, air and traffic impacts on the nearby East Boston community. Comprehensive environmental monitoring and implementation of necessary mitigation measures will ensure that construction impacts of the Airside Project, in combination with other past, present and proposed projects, are not significant.

8 Preferred Alternative and Mitigation

Key Points

This Chapter summarizes the principal findings from the relevant analyses presented in the Airside Improvements Planning Project Draft Environmental Impact Statement/Environmental Impact Report (Airside Project Draft EIS/EIR) and this Supplemental Draft EIS/Final EIR (Supplemental DEIS/FEIR) and the basis for the selection of the Preferred Alternative. Chapter 8 also presents Massport's and FAA's proposed mitigation program. The Executive Office of Environmental Affairs (EOEA) May 7, 1999 Certificate required Massport to commit to a number of "concrete mitigation measures … that will maintain or reduce the existing envelope of cumulative environmental impacts from airport operations." Specific measures identified by the Secretary are addressed in this Chapter, as well as, Massport's mitigation commitments for project related impacts, which are set out in Section 8.7, Proposed Section 61 Findings.

- Massport selected Alternative 1A (which includes all actions except Peak Period Pricing) as the Preferred Alternative because it will provide significant delay reduction benefits through measures that will also provide certain environmental benefits. The environmental impacts that will result from the Preferred Alternative will be mitigated. The taxiway improvement concepts will also improve airfield safety and efficiency. Additionally, delay reductions are achieved without imposing the economic costs on regional carriers and small communities that are associated with Alternative 1, which includes Peak Period Pricing.

- The operational analysis indicates the following about the Preferred Alternative:

  - A unidirectional Runway 14/32 produces significant delay reduction benefits under all future forecast scenarios, as well as under current activity levels.

  - Greater use of regional transportation options, such as regional airports and high speed rail, provides a benefit by accommodating a greater share of the region's intercity travel demand. However, regional transportation options do not eliminate the principal cause of delays at Logan, i.e., the lack of a third available runway during northwest wind conditions.

  - The Taxiway Improvements, and most importantly the addition of the Centerfield Taxiway, contribute to delay reduction across all future forecast scenarios. In addition, the taxiway improvements will enhance safety and reduce

the potential for runway incursions and wingtip conflicts, while simplifying the taxiway layout and reducing congestion.

- Reducing approach minimums on runways 15R, 22L, 27 and 33L will provide delay reduction and safety enhancement benefits by increasing runway availability in Instrument Flight Rules (IFR) weather.

- The current and projected near-term hourly demand profile and level of aircraft operations at Logan, which are consistent with 29M Low Fleet conditions, do not support implementation of Peak Period Pricing. In the 29M Low Fleet scenario, Peak Period Pricing is not an effective delay reduction tool because airline overscheduling does not significantly contribute to Logan delays in these conditions. It produces only minimal delay reduction in Low Fleet conditions, while imposing costs on certain regional carriers and New England communities that depend on Logan for air service. An appropriate Peak Period Monitoring System will allow Massport to identify conditions when airline overscheduling could come into effect and to take timely remedial action.

- If Runway 14/32 had been available for use in 1998, total delays would have been reduced by 32 percent. Delays in Visual Flight Rules (VFR) conditions would have been reduced by 69 percent and delays during northwest wind conditions would have been reduced by nearly 90 percent.

- The environmental analysis indicates the following:

  - The Preferred Alternative provides flexibility in runway selection and hence a greater opportunity to achieve Preferential Runway Advisory System (PRAS) long-term and short-term noise goals. With unidirectional Runway 14/32 in place, the opportunity to achieve long-term PRAS goals nearly doubles for all fleet scenarios compared to the No Action Alternative.

  - Consistent with improved PRAS achievement, the Preferred Alternative reduces the population exposed to day-night sound levels (DNL) greater than or equal to 70 dB. The trade-off for reducing populations exposed to the highest noise levels is an increase in the number of people located within the 65 to 70 dB DNL contour. Residential sound insulation will be provided to mitigate this impact, to the extent that federal funding is available.

  - Regardless of the forecast activity scenarios, without Runway 14/32 noise for the most severely affected populations will substantially worsen over time. Runway 14/32 provides a unique opportunity to reduce the number of people subjected to the highest noise impacts.

  - In addition to reducing noise exposure at the highest DNL levels, the Preferred Alternative allows for a more balanced geographic distribution of jet operations. Under the 37.5M High scenario, the Preferred Alternative results in 41 percent of jets utilizing runways affecting communities north and south of the airport,

compared to 91 percent for the No Action Alternative. Conversely, the percentage of jets flying over water increases significantly from 6 percent in the No Action Alternative to 30 percent with the Preferred Alternative.

- ❑ Runway 14/32 and the Taxiway Improvements significantly reduce ground noise impacts for communities most affected by ground taxi noise.
- ❑ The Preferred Alternative provides air quality benefits, when compared to the No Action Alternative, by reducing aircraft delays.
- ❑ The Preferred Alternative has been reviewed in accordance with the Federal Executive Order 12898 and the applicable US DOT Order. After taking into account mitigation measures, the Preferred Alternative will not result in a disproportionate impact to minority and/or low-income populations.
- ❑ No impacts to wetlands will result from the construction of Runway 14/32 or the Taxiway Improvements.
- ❑ No long-term impacts on water quality will result from Runway 14/32 or the Taxiway Improvements.
- ❑ Construction of the Centerfield Taxiway and Taxiway Delta will alter portions of grassland that serve as a habitat for the state-listed endangered upland sandpiper. The Massachusetts Natural Heritage and Endangered Species Program (NHESP) issued draft permit conditions to Massport that will be used to develop a mitigation plan to address this impact.
- ❑ The Preferred Alternative will not incorporate land from a Section 4(f) resource. In addition, neither proposed sound insulation activities nor mitigation will affect the normal activity or aesthetic value of any public park, refuge, or historic site.
- ❑ All short-term construction impacts can and will be mitigated.

■ The project-specific mitigation program addresses all potential adverse environmental impacts associated with the Preferred Alternative:

- ❑ Runway 14/32 will be designed, constructed and at the request of Massport be operated by the FAA to handle only over-water operations (i.e., unidirectional use). Massport will light, mark and instrument the runway to reflect non-use of Runway 32 for departures and non-use of Runway 14 for arrivals. As a further reinforcement of the unidirectional restriction, Massport will construct only a parallel taxiway on the 14 end to accommodate over-water departures.
- ❑ To the extent that federal funding is provided, the proposed sound insulation program will include all residences newly included within the Preferred Alternative's 65 dB DNL contour when compared to the No Action 65 dB DNL contour for the 29M Low Fleet scenario. Furthermore, Massport and the FAA will continue to sound insulate eligible residences through the current 2-year sound

insulation program as presented in the *Logan Airport 1999 Environmental Status and Planning Report*.[1]

- ❑ Relocation assistance will be provided to eligible tenants of Building 60.
- ❑ The potential loss of upland sandpiper habitat will be mitigated by enhancing off-site habitat, altering airfield mowing procedures, and implementing an on-airfield reconnaissance program.
- ❑ During the construction period, an extensive array of traffic, water quality, air quality and noise mitigation measures will be employed to mitigate temporary construction impacts.

Since the publication of the Airside Project Draft EIS/EIR, Massport has developed certain additional mitigation commitments including:

- A PRAS Monitoring System designed to gather data and report on the actual achievement of PRAS. The objective of this system is to enhance the attainment of the PRAS goals and provide a broader platform for disclosure of the monitoring results.
- A Peak Period Monitoring System to determine when airline overscheduling becomes a significant contributor to delays.
- A Peak Period Pricing exemption program that will reduce the expected degree of service disruption to eligible New England communities, without undermining the Program's delay reduction benefits.
- Steps to be taken by Massport, in cooperation with other state transportation agencies, to ensure that the Worcester, Manchester and T.F. Green Airports operate jointly with Logan Airport as the key elements in an efficient and environmentally balanced regional air transportation network.
- While not related to Airside Project impacts, Massport will continue discussions with air carriers with t he goal of reducing the use of hushkitted Stage 3 aircraft at Logan.

1 *The Logan Airport 1999 Environmental Status and Planning Report*, prepared for Massport by Vanasse Hangen Brustlin, Inc., October 15, 2000

8.1 Introduction

The Airside Project is intended to reduce current and projected levels of aircraft delay and enhance operational safety at Logan. A range of improvement concepts to accomplish these objectives was evaluated in the Airside Project Draft EIS/EIR and a comparative analysis was conducted from both an operational and environmental perspective.

The proposed improvement concepts include:

- Construction of a unidirectional Runway 14/32;
- Construction of a Centerfield Taxiway;
- Extension of Taxiway Delta;
- Realignment of Taxiway November;
- Optimization of taxiways in the southwest corner of the airfield;
- Reduction in approach minimums on Runways 22L, 27, 15R, and 33L; and
- Peak Period Pricing.

The analytical framework for assessing these concepts was structured to provide a comprehensive assessment of alternative packages as shown in Table 8.1-1.

Table 8.1-1

Peak Period Pricing	■		■	■	

The comparative benefits and impacts of the different alternatives were fully described in Chapters 4, 6, and 8 of the Airside Project Draft EIS/EIR. After careful review in the Airside Project Draft EIS/EIR of the extent and causes of delays at Logan and the results of each Alternative's comparative benefits, Alternative 1A was selected as the Preferred Alternative because:

- It significantly reduces the current level of delay and delay for all future scenarios without imposing the economic costs associated with Peak Period Pricing on regional carriers and the communities they serve.

- By reducing delays, it achieves certain environmental benefits that include improved air quality and a reduction of noise for the most severely impacted communities, while causing minimal environmental impacts, all of which will be mitigated.

This chapter presents a summary of the benefits and impacts of the Preferred Alternative, compares these results to the consequences of doing nothing (No Action Alternative), and summarizes the Airside Project mitigation and permitting requirements.

8.2 Preferred Alternative

The analysis in the Airside Project Draft EIS/EIR provided the analytical context for the selection of Alternative 1A as the Preferred Alternative for reducing current and projected levels of aircraft delay and enhancing operational safety at Logan. The Preferred Alternative achieves significant delay reduction and safety benefits under all future forecast scenarios, reducing total annual delays by 27 to 31 percent and VFR runway delays by 48 to 56 percent when compared to the No Action Alternative. Implementation of the Preferred Alternative will allow Massport to increase the operational efficiency and safety of the airfield, reduce existing delay, and accommodate the expected future growth in aviation activity that is vital to the regional economy.

By improving airside operating conditions and reducing the amount of time aircraft are delayed in the air or on the ground, the Preferred Alternative reduces the environmental impact of aircraft operations. This alternative will result in improved air quality over No Action conditions, an increase in the number of aircraft operations on over–water flight paths, a greater ability to meet PRAS noise goals, and reduced noise impacts for the most severely affected populations in East Boston, Revere and Winthrop. With the construction, environmental and sound insulation mitigation proposed by Massport, the short-term and long-term environmental impacts associated with the Preferred Alternative will be mitigated.

The Preferred Alternative, Alternative 1A, consists of the following improvements:

Unidirectional Runway 14/32

A new 5,000-foot unidirectional runway will be constructed along the southwestern edge of the airport. The Runway 14/32 layout will be designed by Massport and operated by the FAA only as a unidirectional runway. All arrivals will occur over Boston Harbor to the Runway 32 approach end and all departures will occur from the Runway 14 end and head out over the harbor. Unidirectional Runway 14/32 addresses the principal cause of delay at Logan – the substantial drop in capacity that occurs when moderate to strong northwest/southeast winds force the airport to operate with fewer than three runways – by providing a second effective parallel runway in the northwest/southeast orientation. In calm winds, availability of another three-runway configuration that includes unidirectional Runway 14/32, would also provide the FAA with greater flexibility to shift operations away from Runways 4L/22R and 4R/22L and increase the number of operations over the water. This would allow for a more equitable distribution of operations consistent with the PRAS noise abatement goals, and provide relief to noise-affected communities to the north and south of the Airport. Construction of the unidirectional runway is estimated to take approximately one year, and would begin after the receipt of all necessary federal and state approvals.

Centerfield Taxiway

A 9,300-foot taxiway will be constructed between Runways 4L/22R and 4R/22L. The Centerfield Taxiway will: (1) reduce taxiway congestion, thereby enhancing the general safety of airside operations; and (2) facilitate more efficient movement of aircraft between terminal areas and runways during takeoff and landing procedures, thereby reducing delays, ground noise and air emissions.

Other Taxiway Improvements

Taxiway crossings and ground taxiing movements will be improved to enhance airfield safety and operating efficiencies by:

- Reconfiguring the Southwest Corner Taxiway System to streamline taxiway flow in a very complex area for ground operations. The taxiway reconfiguration would improve access in the areas of runway ends 9, 4L and 4R, and several of the surrounding taxiways by isolating the lines of traffic flow from each other.

- Extend Taxiway Delta to Runway 4R/22L by constructing an additional 2,000 feet of taxiway between Runway 33L and Runway 4R.

- Realign Taxiway November between Runway 15L/33R and Runway 33L/15R and eliminate Taxiway Tango. The realignment would also change the location of the intersection with Taxiways Alpha and Kilo by removing the intersection after the curve to simplify the crossing of these taxiways.

Operational Improvements

The proposed action will reduce the approach minimums on Runways 22L and 27 to ILS Category I values and on Runways 15R and 33L to ILS Category III values, consistent with the capabilities of the existing and planned navigational equipment. Implementation of reduced minimums is solely within the FAA's jurisdiction.

Peak Period Pricing is not included in the Preferred Alternative because airline over-scheduling is not currently a problem at Logan. Further, the delay reduction benefits associated with Peak Period Pricing come at a cost to passengers, communities and the air carriers. If airline overscheduling becomes a significant contributor to Logan delays in the future, Massport recognizes the benefits of Peak Period Pricing and will implement an appropriate program at that time. Chapter 4 of this document describes the Peak Period Monitoring System designed by Massport to determine when delays due to overscheduling are severe enough that a peak period pricing program would be appropriate. The commitment to initiate and maintain the Peak Period Monitoring System is a specific project mitigation measure.

Table 8.4-1
Summary of Preferred Alternative by Construction Elements

Construction Element	Construction Cost Estimate[3] ($ millions)	Estimated Construction Period (Days[1])
Unidirectional Runway 14/32	$33	300
Centerfield Taxiway	$20	See Note 2
Southwest Taxiway System Reconfiguration	$14	240
Taxiway Delta Extension	$6	180
November Taxiway Realignment	$3	180
Total	$76	Phased over ± 5 years

1 Days are consecutive calendar days, inclusive of Saturdays and Sundays. Does not include winter construction shut down period.
2 Construction of the northern segment of Centerfield Taxiway is estimated to take 180 days; construction of the southern segment Centerfield Taxiway is estimated to take 210 days. There is some overlap of the two construction periods.
3 Costs are for construction only and exclude mitigation costs.

8.3 Summary of Delay Reduction Benefits

The FAA's and US DOT's current and historic delay statistics confirm that Logan Airport is unable to accommodate existing demand levels without incurring significant levels of delay. As demand continues to grow, airfield congestion and delays at Logan will worsen if effective measures for dealing with increased demand are not implemented.

An evaluation of the No Action Alternative illustrates the consequences of doing nothing:

- If no actions are taken, Logan's annual runway and taxiway delays will increase from 142,000 hours in 1998 to as much as 363,000 hours in the 37.5M High Fleet scenario.

- If no airfield improvements are made, the ability to improve PRAS goals will diminish over time. As demand increases, dependence on the north/south operation of the airport is projected to grow to nearly 90 percent.

While Massport cannot entirely eliminate delays at Logan, an evaluation of the Airside Project Alternatives indicates that the Preferred Alternative is an effective measure for reducing current delay, increasing operational efficiency and enhancing safety. Under the 29M Low Fleet scenario, which is most similar to current conditions at Logan, the Preferred Alternative reduces total annual delay (runway and taxiway) by 27 percent, or 46,100 hours. Unidirectional Runway 14/32 produces a consistent and significant delay reduction benefit under all future fleet scenarios, without imposing a disproportionate economic burden on regional carriers.

Runway 14/32 reduces annual delay primarily by reducing delays on days when moderate to strong northwest or southeast winds prevent air traffic controllers from using existing high capacity runway configurations. If Runway 14/32 had been available in 1998, delays would have been reduced by nearly 90 percent in northwest wind conditions.

While the level of taxiway delays at Logan is not as high as those delays associated with runway constraints, taxiway delays impede airfield efficiency, increase ground noise and increase air emissions. The airfield delay analysis indicates that taxiway improvements will provide substantial delay reduction and reduce the risk of runway incursions. While the taxiway improvements provide the greatest reduction in taxiway delays, the addition of unidirectional Runway 14/32 also contributes to taxiway delay savings by permitting a shift in runway usage patterns that allows the use of more efficient taxiway configurations.

The taxiway improvements, and most importantly the Centerfield Taxiway, contribute to delay reduction across all future forecast scenarios. The delay reduction hours attributable to the taxiway improvements in the 29M Low Fleet scenario are approximately 21,900 hours.

8.4 Summary of Environmental Impacts

The Airside Project Draft EIS/EIR presented a comprehensive analysis of environmental issues in response to the federal and state scoping documents. This section of the Supplemental DEIS/FEIR presents a summary of the results of the environmental analysis for the Preferred Alternative as compared to the No Action Alternative under future fleet scenarios.

8.4.1 Air Quality

There are no negative air quality impacts associated with the Preferred Alternative. When compared to the No Action Alternative, the Preferred Alternative provides air quality benefits. The Preferred Alternative is expected to generate lower amounts of total carbon monoxide (CO), oxides of nitrogen (NOx), volatile organic compounds (VOCs), odor-causing hydrocarbons, and PM_{10} emissions than the No Action Alternative. The results of the dispersion modeling analysis shows that the Preferred Alternative is expected to result in no violations of the National Ambient Air Quality Standards (NAAQS). This pattern is the same for all future fleet scenarios and is largely attributable to delay reductions in airside operations associated with the Preferred Alternative.

8.4.2 Noise

The Preferred Alternative provides for increased flexibility in runway selection. This leads to a more equitable distribution of noise impacts and a greater ability to meet PRAS noise abatement goals than the No Action Alternative. If the Preferred Alternative is implemented, achievement of the annual PRAS goals is expected to nearly double for all fleet scenarios. The delay modeling also shows that the Preferred Alternative produces similar results for all future scenarios for the short-term dwell (one day) and persistence (three-day) PRAS goals.

The ability of Runway 14/32 to increase the opportunity to better meet PRAS runway-use goals is also reflected in the area-wide cumulative noise exposure contours for in-flight noise and estimates of the number of people residing within those contours. The Preferred Alternative provides a substantial reduction in population exposed to day-night sound levels (DNL) greater than or equal to 70 dB. For future fleet scenarios, the reductions are significant, ranging from 70 to 81 percent for DNLs greater than or equal to 75 dB, and 39 to 43 percent for values of 70 dB or greater.

In addition to reducing noise exposure at the highest DNL levels, the Preferred Alternative allows for a more balanced geographic distribution of jet operations. Under the 37.5M High scenario, the Preferred Alternative results in 41 percent of jets utilizing runways affecting communities north and south of the airport, compared to 91 percent for the No Action Alternative. Conversely, the percentage of jets flying over water increases significantly from 6 percent in the No Action Alternative to 30 percent with the Preferred Alternative.

For both the Preferred Alternative and the No Action Alternative, the average changes in population within the 65 dB DNL contour are small. The population within the 65 dB DNL increases in Chelsea (by 244 people) and, to a lesser degree, in portions of East Boston (by 139 people) and South Boston - west of D Street (by 32 people), when compared to the No Action Alternative under the 29M Low Fleet scenario. These population increases result from increased use of Runways 15R/33L and Runway 27 departures, consistent with the PRAS runway use goals.

The analysis of ground taxi operations indicates that the noise from ground operations is significantly less than the noise from in-flight operations**.** The Preferred Alternative would, however, produce a significant reduction in ground taxi noise for communities located to the northeast of the airport (the Bayswater section of East Boston and the Court Road section of Winthrop), with smaller reductions at Jeffries Point.

8.5 Summary of Mitigation for the Preferred Alternative

This section presents a summary of the environmental and construction impacts associated with implementation of the Preferred Alternative and presents proposed measures to mitigate these impacts, where applicable. For this Supplemental DEIS/FEIR, the preliminary mitigation plan presented in the Airside Project Draft EIS/EIR is repeated, and the additional mitigation measures are presented. The project-specific and other mitigation commitments include:

- Project-Specific Mitigation measures are as follows:
  - **Reinforce Unidirectional Restriction** for Runway 14/32 operations.
  - **Sound Insulation Program** for those eligible residences located within the 65 dB DNL contour (29M Low Fleet). These areas include portions of Chelsea, East Boston and South Boston. For the eligible residences, the FAA will fund building code upgrades, to the extent necessary, to implement sound insulation improvements.
  - **Airport Tenant Relocation Assistance.** The only relocation required for construction of Runway 14/32 involves the tenants of Building 60 in the South Cargo Area. Massport will provide relocation assistance as required under applicable law to mitigate impacts.
  - **Upland Sandpiper Habitat Enhancement Plan** including: Alteration of existing airfield grassland mowing procedures to encourage the use of non-construction areas; implementation of a pre-construction and an on-going pre-mowing upland sandpiper reconnaissance program; and restoration of off-site habitat.
  - **Construction Mitigation** including Massport's required Construction Mitigation Program, and adherence by Massport and construction contractors to the Clean Air Construction Initiatives.

- Other Mitigation Commitments include the following:

  - **PRAS Monitoring and Reporting.** Massport is committed to more frequent and comprehensive PRAS monitoring and public reporting.
  - **Peak Period Monitoring Program.** Massport is proposing an airline schedule monitoring system, and is committed to implementing Peak Period Pricing if airline overscheduling emerges as a source of future delays.
  - **PRAS Nighttime Over-Water Preference Routing.** Massport will encourage the FAA to continue the practice of initiating over-water routing preferences as soon after 11:00 PM as practicable.
  - **Seek to Reduce Use of Hushkitted Aircraft at Logan.** Massport will continue to work with air carriers to encourage the use of full Part 36 (Stage 3) new technology aircraft.
  - **Regional Transportation Steps.** Massport supports the regionalization of New England's transportation network and continues to work with aviation transportation agencies including the FAA, the Massachusetts Aeronautics Commission (MAC), other New England State Aviation Directors, and the regional airports, to ensure the efficient use of the region's transportation infrastructure. Massport, along with the FAA and the regional airport directors, will conduct the *New England Airports System Study*. This study will evaluate the potential for international, charter, and cargo services at each of the regional airports; evaluate capacity issues at each of the regional airports; and consider the development of high occupancy vehicle/ground transportation and rail alternatives to improve access to the regional airports.

8.5.1 Project Specific Mitigation

The following section outlines the project specific mitigation proposed as a component of the Airside Improvements Planning Project. Project specific mitigation measures are described according to the affected environmental categories of noise, air quality, land use/socioeconomic, air quality, vegetation and wetlands, wildlife, water resources and soils. An extensive series of construction-related mitigation measures are presented in detail in Section 8.5.2. In addition, Massport has proposed other mitigation measures, that, while not specifically related to the Airside Project, would be implemented concurrently with the Preferred Alternative. These other measures are discussed in Section 8.5.3.

8.5.1.1 Unidirectional Commitment

The Runway 14/32 component of the Preferred Alternative has been conceived and proposed by Massport to accommodate unidirectional operations only. As a unidirectional runway, all aircraft arrivals would occur over Boston Harbor to the Runway 32 approach end and all departures would initiate from the Runway 14 end heading out over Boston Harbor. One of the issues raised in the May 7, 1999 EOEA Certificate and addressed during the SDEIS Panel process was a review of how the commitment to this unidirectional operational limitation for proposed Runway 14/32

could be reinforced. This section repeats a discussion of this issue before the Panel and constitutes a confirmation of Massport's commitment in this area.

Reinforcement of the unidirectional limitation occurs on three different levels. The first level centers on operational considerations. Massport will construct, mark and light Runway 14/32 to accommodate unidirectional operations only. In addition, the Hyatt Conference Center (174 feet high) is located within 1,300 feet of the west end of proposed Runway 14/32 and thereby obstructs the pertinent approach requirement, precluding arrivals from the west to the 14 approach end (see 14 CFR Part 77.25(d)). Another factor limiting westerly operations on Runway 14/32 is the lack of available facilities to allow aircraft to taxi to the 32 end. Without such facilities, aircraft would be required to use the Runway to taxi to the 32 end in order to position for takeoff in a westerly direction. Such a requirement would limit significantly the delay reduction benefits associated with utilizing Runway 14/32 for 32 departures.

The second level of reinforcement for the unidirectional limitation on Runway 14/32 is the environmental permit process itself. Approval under both federal and state environmental review processes is sought for a unidirectional runway only. Furthermore, the unidirectional limitation is being designated in the federal and state environmental review documents as a mitigation measure. This designation is supported by the goals of: (i) maximizing over water operations, thereby limiting operational impacts over residential areas, and (ii) allowing better attainment of Preferential Runway Advisory System (PRAS) goals. The unidirectional limitation as a Project mitigation element will be included as one of Massport's findings under M.G.L. Section 61 and is anticipated to be an element of both the federal Record of Decision and the certificate of the Massachusetts Secretary of Environmental Affairs, thus providing a further level of reinforcement of this limitation.

The first two levels of reinforcement discussed above entail physical restraints and governmental determinations within the jurisdiction of both the Federal Aviation Administration (to be addressed in the federal Record of Decision) and the Massachusetts Executive Office of Environmental Affairs (through the Secretary's Certificate on the Final EIR). A third level of reinforcement would provide an additional, representative governmental body and/or appropriate representative community groups, with contractual rights to enforce the unidirectional limitation. Massport reaffirms its willingness to enter into an appropriate contractual agreement with another governmental unit and/or representative community group. This agreement would (i) reiterate the unidirectional restrictions outlined above (e.g., limited markings and lighting, and no taxiway to accommodate takeoffs from the 32 end), (ii) allow Runway 14/32 to be constructed and operated as a unidirectional runway only, and (iii) provide such entity or group(s) with standing and a contractual mechanism to enforce the unidirectional commitment.

8.5.1.2 Noise

The Preferred Alternative includes construction of unidirectional Runaway 14/32, which provides flexibility in runway selection, and hence a greater ability to achieve PRAS goals. In order to maximize over-water operations and achieve the other PRAS-related benefits of Runway 14/32, it has been designed and will be permitted for unidirectional use only, i.e., it will only accommodate over-water arrivals and departures.

By allowing better achievement of PRAS goals, implementation of the Preferred Alternative significantly reduces the most severely noise-impacted populations within the 70 and 75 dB DNL contours in East Boston, Winthrop and Revere. However, by increasing utilization of Runway 15/33 to levels more consistent with PRAS goals, the Preferred Alternative will also increase the affected population within the future 65 dB DNL contours compared to the No Action Alternative and to 1998 conditions. Massport proposes to mitigate these impacts by providing sound insulation to affected residences in Chelsea, East Boston and South Boston that fall within the 65 dB DNL contour for the Preferred Alternative as defined by the 29M Low Fleet scenario. The estimated number of dwelling units listed in Table 8.5-1 reflects the total number of dwelling units that will be sound insulated as a result of the Preferred Alternative 29M Low DNL contour. For the project-eligible residences, the FAA will fund building code upgrades, to the extent necessary, to implement sound insulation improvements. The number of residences to be included within the noise mitigation program will be determined based on a more detailed block-by-block analysis to be performed during implementation.

Table 8.5-1
Proposed Sound Insulation Mitigation

Community	Estimated Number of Dwelling Units
Chelsea	1,100 to 1,200
East Boston	150 to 200
South Boston	25 to 50
Approximate Total	**1,275 to 1,450**

In summer 2000, Massport submitted a new sound insulation program based on the 1998 65 dB DNL contour with terrain-adjusted exposure levels to the FAA New England Regional Office. The FAA approved the new sound insulation contour for a two-year period. This sound insulation program is funded and is underway.

8.5.1.3 Land Use/Socioeconomic

Implementation of the Preferred Alternative is restricted to activities and purposes compatible with normal airport operations and existing land use plans. Construction of the runway and taxiway improvements will occur on the existing airfield.

Construction of unidirectional Runway 14/32 requires the demolition of Buildings 60 and 61 in the South Cargo Area. The tenant of Building 61 (the U.S. Postal Service) has plans to vacate the building, independent of the Airside Project. Therefore demolition of this building would not require relocation assistance. The leases for Building 60 extend beyond the proposed 2003 construction start of the Preferred Alternative. Therefore, relocation assistance for eligible tenants of Building 60 will be provided in accordance with applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, as amended, and specifically Part 24 of 49 CFR and M.G.L. Chapter 79A and implementing regulations. Relocation assistance measures may include relocation advisory services and payments for moving and relocation costs, as applicable. Relocation resources would be available to all eligible business relocatees without discrimination.

8.5.1.4 Air Quality

The emissions inventory for carbon monoxide (CO), oxides of nitrogen (NOx), and volatile organic compounds (VOC) indicates that the Preferred Alternative is expected to generate the least amount of emissions of all Alternatives evaluated, including the No Action Alternative. The dispersion modeling results for the Preferred Alternative indicate that predicted levels of CO, NO_2 and PM_{10} are expected to be well within air quality standards and guidelines, under all future fleet scenarios analyzed. Therefore there are no negative air quality impacts associated with implementation of the Preferred Alternative. Rather, the Preferred Alternative provides an air quality benefit when compared to the No Action Alternative. This outcome is attributable to the delay reduction benefits associated with the Preferred Alternative.

To comply with the Clean Air Act Amendments of 1990 (CAAA), the FAA must determine if the proposed action is consistent with the State Implementation Plan (SIP) for ozone, since Logan is located in a non-attainment area for this pollutant. FAA procedures for compliance with General Conformity regulations mandated by Section 176(c) of the CAAA require that the FAA compare the emissions resulting from the Preferred Alternative against those emissions that would have occurred under the No Action Alternative.

Based on the analyses of NOx and VOCs (see Tables 6.4-5 and 6.4-6, respectively), FAA has determined that for all future conditions analyzed, the Preferred Alternative's net annual emissions (Preferred Alternative emissions minus No Action emissions) will be less than the applicable NOx and VOC emission levels in 40 CFR 93.153(b). In addition, FAA analysis of these levels shows that the Preferred Alternative would not be "regionally significant" because it would not account for 10 percent of the total emissions

inventories for NOx or VOC in the Boston ozone non-attainment area. Accordingly, FAA has determined that further analysis of the Preferred Alternative under Section 176(c) of the CAAA is not needed and that the implementation of the Preferred Alternative is presumed to conform to the SIP.

For NEPA purposes, FAA must also assess the air quality impacts of project alternatives. Dispersion modeling for the Preferred Alternative and the No Action Alternative shows that the proposed project would not exceed any National Ambient Air Quality Standards (NAAQS). Accordingly, FAA has determined that the Preferred Alternative would not cause significant air quality impacts.

8.5.1.5 Vegetation and Wetlands

All construction associated with the Preferred Alternative is confined to upland portions of the airfield. There will be no loss of wetlands as a result of the implementation of the Preferred Alternative. During construction, sediment and erosion controls will be implemented within the 100-foot buffer zone of the coastal bank. All areas disturbed by construction will be stabilized with vegetation common to the airfield once re-grading is completed.

8.5.1.6 Wildlife

Construction of the Centerfield Taxiway and the Taxiway Delta extension will result in the conversion of approximately 37 acres of grassland to paved surface thereby eliminating this area as habitat for the state-listed endangered upland sandpiper. Massport is working with the Massachusetts Natural Heritage and Endangered Species Program (NHESP) to develop a mitigation plan that will address this impact. The mitigation plan comprises the following elements:

- Off-site habitat enhancement.
- Alteration of existing airfield grassland mowing procedures prior to the spring arrival of the upland sandpiper to encourage occupation of other areas of the airfield rather than the construction area.
- Implementation of a pre-construction and an ongoing pre-mowing upland sandpiper reconnaissance program to ensure that no individual birds remain in the areas being mowed.

Enhancement of bird habitat at Logan is not feasible due to the significant potential of increased aviation hazards. As part of the Conservation and Management Permit process under the Massachusetts Endangered Species Act (MESA), Massport has worked closely with the NHESP to develop a comprehensive onsite and offsite mitigation program to provide a “net benefit to the local population” of upland sandpipers. The offsite mitigation is expected to involve Massport funding of a grassland restoration / habitat enhancement program at Camp Edwards on Cape Cod. Under this program, Massport would provide funds to the Massachusetts National Guard (MNG) for the restoration of the former upland sandpiper habitat. A Memorandum of Understanding (MOU) is under

discussion among Massport, MNG and NHESP to ensure effective implementation of the program.

8.5.1.7 Water Resources

Construction of the runway and taxiways will result in a slight increase (3.8 percent) in peak runoff to tidal waters. Peak discharges will be minimized through the use of grassed swales and infiltration of runoff. No long-term impacts to water quality are anticipated. The existing stormwater drainage system will be reconfigured slightly to accommodate runoff from the runway and taxiway improvements. A low-flow water quality treatment structure may be incorporated into the existing system to handle the first flush runoff from portions of the airfield, if feasible. Sediment and erosion controls will be installed and maintained during all portions of construction to minimize adverse impacts. Construction will be phased to minimize the extent of bare soil at any one time. All new runway and taxiway construction within areas subject to DEP's Stormwater Management Policy will be consistent with applicable policies and performance standards.

8.5.1.8 Soils

Disposal of soils excavated for runway and taxiway construction will be regulated under the Massachusetts Contingency Plan (MCP) (310 CMR 40.0000) and further reviewed for consistency with Massport's Soil Management Plan developed for the Logan Modernization projects.

8.5.2 Construction Mitigation

An extensive array of construction period mitigation measures is proposed for the Airside Project improvements that comprise the Preferred Alternative. Measures that specifically address safety, traffic, air quality, and noise will be written into the contract documents and specifications governing the contractors and subcontractors constructing the improvements. As in the Logan Modernization Program and other major construction projects at the airport, Massport will employ a team of on-site resident engineers and inspectors to monitor the contractors' compliance with mitigation measures.

Safety is of paramount concern since major construction will be occurring in proximity to operating runways and taxiways. All construction activity will be governed by the requirements of FAA AC 150/5370-2C *Operational Safety on Airports During Construction*.

Construction mitigation measures in a number of categories are described below.

8.5.2.1 Construction Traffic Operations

- Construction vehicles will be required to use State highways or Logan roadways, including the Ted Williams Tunnel, except when seeking access to local businesses. A clause to this effect will be inserted in all construction contracts relating to the Airside Project improvements.

- Truck routes for Logan projects that minimize impacts on the local communities are well established. Construction vehicles would be restricted from using Neptune Road, Maverick Street, and Porter Street in East Boston. Designated truck routes will be specified in all construction contracts.

- Construction employee parking spaces will not be permitted on the construction site nor will provisions be made for them elsewhere on-airport with the exception of a small number of spaces for supervisory personnel. It is expected that construction workers will access the airport via public transportation or via shuttle buses from off-airport parking areas.

- Police details will be employed at appropriate locations on the airport to manage traffic and ensure public safety.

8.5.2.2 Construction Air Quality

- As part of Massport's continued commitment to reduce impacts to the environment, Massport will require contractors to retrofit their heavy construction equipment with advanced pollution control devices during construction in accordance with DEP's Clean Air Construction Initiative. Contractor-owned equipment such as front-end loaders, backhoes, cranes and excavators will be retrofitted with oxidation catalysts. This device filters out and breaks down hydrocarbons, particulate matter and carbon dioxide associated with diesel emissions.

- During the construction process a regular program of street sweeping will minimize dust from construction vehicle movements on airport roads.

- Fugitive dust also will be controlled with water spray as needed during demolition and construction; no chemical soil stabilizers will be used.

- All trucks hauling demolition materials and excavate from the site will be covered and their wheels will be washed prior to leaving the construction site.

8.5.2.3 Construction Noise

General construction noise will be limited using techniques such as:

- Use of: (1) concrete crushers or pavement saws for building demolition or similar construction activity; (2) local power grid to reduce the use of generators, to the extent practicable and feasible.

- Attaching: (1) intake and exhaust mufflers, shields, or shrouds; (2) noise-deadening material to inside of hoppers, conveyor transfer points, or chutes.

- Maintaining equipment to ensure peak performance.

- Limiting (1) the numbers and duration of equipment idling on the site; (2) the use of annunciators or public address systems; (3) the use of air or gasoline-driven hand tools.

- Configuring, to the extent feasible, the construction site in a manner that keeps loud equipment and activities as far as possible from noise-sensitive locations.

When construction is scheduled during the nighttime hours and near community sensitive areas (e.g., East Boston and Winthrop) the following noise mitigation measures will be employed:

- The use of backup alarms for all pieces of equipment will be prohibited, to the extent appropriate. The contractors will be required to provide additional laborers to assure that equipment backup safely and comply with OSHA regulations.

- Trucks delivering bituminous concrete or other materials will be prohibited from slamming their tailgates to clean out truck beds after dumping.

- During paving operations, contractors will be required to turn off their vibratory compactors prior to exiting off of the newly placed pavement and onto the old existing pavement.

- Further noise control options will be evaluated during the ongoing project design to define their effectiveness and feasibility. Appropriate operational specifications and performance standards will be incorporated into the construction contract documents.

8.5.2.4 General Project Construction Mitigation

All construction activity associated with the Preferred Alternative will be governed by FAA Advisory Circular 150/5370-2C, Operation Safety on Airports During Construction. In addition, Massport has developed a number of mandatory construction mitigation procedures for all construction contractors. Massport will be responsible for overseeing all activities related to the Airside Project improvements including the following management practices:

- Full coordination with the CA/T Project, and with all relevant agencies including the FAA, MBTA, Massachusetts Turnpike Authority, Massachusetts DEP, Massachusetts Coastal Zone Management (CZM), Massachusetts Water Resources Authority (MWRA), City of Boston, Boston Water and Sewer Commission (BWSC), and utility companies, as appropriate.

- Preparation of detailed pre-construction plans for traffic maintenance, construction specifications for contractors, and coordinated scheduling of all construction activities (as well as the other measures noted in the ground transportation section above).

8.5.3 Environmental Justice

The Preferred Alternative has been reviewed in accordance with the Federal Executive Order 12898 and the applicable US DOT Order. After taking into account mitigation measures, the Preferred Alternative will not result in a disproportionate adverse impact to minority and/or low-income populations.

- There is no disproportionate high and adverse impact caused by the Preferred Alternative. Adverse noise impacts of the Preferred Alternative are not predominately borne by a minority or low-income population. Only 21 percent of the population within the 65 dB DNL contour is minority, compared Suffolk County, which is 38 percent minority. Less than 2 percent of the population within the 65 dB DNL contour has a household income less than 150 percent of poverty level.

- The additional area within the Preferred Alternative 65 dB DNL contour under the 29M Low Fleet scenario includes a predominantly Hispanic neighborhood in Chelsea which is predicted to experience an increase of 0.6 dB DNL or less. Under FAA's standards, this change is not a significant adverse impact. Nonetheless, mitigation of the increased noise exposure will be provided to the affected community in the form of residential sound insulation.

8.5.4 Other Mitigation Measures

Since the publication of the Airside Project Draft EIS/EIR, Massport has developed proposals for other mitigation measures including:

- PRAS Monitoring and Reporting
- Peak Period Monitoring Program
- Ongoing Discussion with Air Carriers to Reduce Use of Hushkitted Aircraft at Logan
- Regional Transportation Steps

8.5.4.1 PRAS Monitoring and Reporting

The forecast levels of PRAS achievement that are reflected in the Airside Project analysis show continuous improvement from current levels. The analysis presented in Chapter 4 of this Supplemental DEIS/FEIR clearly demonstrates the improvement in PRAS achievement that has taken place since its inception in the early 1980s, and especially since 1996, when the FAA began using the modified version of PRAS. Because Massport is committed to further improvement in PRAS achievement, it has designed protocols for monitoring and reporting PRAS performance. Chapter 4 describes the proposed PRAS Monitoring System and report distribution. In summary, the Massport Quarterly Noise Reports will include a number of new reports and the distribution list will be expanded to include all interested parties. In addition, the annual reports on runway utilization, dwell and persistence will also be included in the ESPR and its Environmental Data Reports (EDR). Over the longer-term, Massport will work with the FAA to design additional reports, which could help enhance the attainment of PRAS.

8.5.4.2 Peak Period Monitoring System and Peak Period Pricing Exemption Program

As part of this Supplemental DEIS/FEIR, Massport completed several analyses that allowed for a more complete understanding of Peak Period Pricing. (These analyses are described in Chapter 4 of this document.) The product of two of these analyses is reflected in Massport's mitigation plan. First, Massport recognizes the delay reduction benefits associated with Peak Period Pricing in an environment characterized by airline overscheduling and is committed to an ongoing program designed to regularly monitor peak period airline schedules. In Chapter 4, Massport identifies a criterion that would initiate of a phased administrative and regulatory process leading to the implementation of a Peak Period Pricing program. Massport's monitoring program, described in Chapter 4, will provide the appropriate mechanism for identifying the point at which the triggering criterion occurs.

Should Peak Period Pricing be invoked, Massport and others are concerned about the detrimental effects such a program could have on New England communities that rely on air service to Logan Airport for access to the national aviation system. As mitigation against the potential economic costs of Peak Period Pricing, Massport has evaluated an exemption program for eligible New England communities. The illustrative program provides a Peak Period surcharge exemption for two roundtrips per day in each eligible market. Consideration will also be given to operational factors, such as the use of the 2,557-foot Runway 15L/33R, that may justify exemptions without jeopardizing the delay reduction benefits of Peak Period Pricing. These exemptions will be included as part of a Peak Period Pricing regulatory proposal and will be subject to public comment and review along with the other elements of the Peak Period Pricing proposal, as required under the Commonwealth's Administrative Procedures Act.

8.5.4.3 Hushkitted Aircraft

As air carriers and cargo operators phased out their remaining Stage 2 aircraft (gross weight > 75,000 pounds), some opted to retrofit their older Stage 2 aircraft with "hushkits", designed to reduce noise levels to meet the Part 36 Stage 3 noise limits. Others replaced their Stage 3 aircraft with quieter, new Stage 3 technology aircraft, resulting in more significant noise abatement benefits. Operators at Logan Airport have done both. Substituting quieter, new Stage 3 technology results in more significant noise reduction benefits.

The reduction in noise exposure that will be experienced as fleet changes continue depends heavily on how many hushkitted aircraft remain in operation over the next few years. One especially promising sign, however, has been the recent fleet conversions by the US Airways and Delta Shuttles. Massport has worked to encourage each carrier to update its fleet from hushkitted Stage 3 Boeing 727-200 aircraft to Stage 3, new-technology aircraft. Subsequent to those discussions, both carriers announced fleet renewal programs. US Airways Shuttle now operates quieter Airbus 320 aircraft and the Delta Shuttle flies Stage 3 Boeing 737-800s. While not related to Preferred Alternative

impacts, Massport will continue to encourage air carriers to reduce the use of hushkitted Stage 3 aircraft at Logan.

8.5.4.5 Regional Transportation Steps

Massport is engaged in promoting increased utilization of regional airports and other travel modes to provide relief to Logan Airport. As an independent authority that owns and operates Logan and Hanscom Field, as well as the Tobin Bridge and many properties in the Port of Boston, and has operational responsibility for Worcester Regional Airport, Massport is just one of many agencies that influence regional transportation policy. With regard to aviation, Massport's primary responsibilities are the provision, operation and maintenance of airport infrastructure at Logan and Hanscom Field, and the operation of Worcester Regional Airport.

Massport and FAA are committed to cooperative transportation planning and are actively working with a broad array of transportation agencies and concerned parties to ensure an integrated, multi-modal regional transportation network. Massport has undertaken several initiatives to advance the role of regional airports in accommodating a greater share of the region's air travel demand. Massport is also an active participant in several interagency transportation planning forums pertaining to alternative intercity travel modes. Massport will also participate in the planned *New England Airports System Study*. Chapter 2 provides a detailed description of Massport's regional transportation efforts and initiatives.

8.5.5 Feasibility Study on NOx Emissions Reduction

The EOEA May 7, 1999 Certificate on the Airside Draft EIS/EIR requested that Massport undertake a feasibility study of implementing measures to reduce NOx emissions at Logan. This study was reported on in the *1999 Logan Airport Environmental Status and Planning Report* (filed in December 2000). A final report recommending NOx emissions reduction strategies will be presented to MEPA by the end of March 2001.

8.6 Permits

The following agency reviews, permits, approvals, and notices may be required for the implementation of the Preferred Alternative (Table 8.6-1).

Table 8.6-1
Project Permits and Approvals[1]

Agency Name	Permit or Action
Project Permits and Approvals	
Federal Aviation Administration	■ Airport Layout Plan (ALP) approval ■ National Environmental Policy Act (NEPA), Record of Decision ■ Airspace Analysis and Determination ■ Notice of Proposed Landing Area Construction or Alteration (14CFR, Part 171)
Massachusetts Executive Office of Environmental Affairs	■ Massachusetts Environmental Policy Act (MEPA) Certification
Massachusetts Coastal Zone Management	■ Federal Consistency Review
Massachusetts Historical Commission	■ Section 106 Review[2]
Commonwealth of Massachusetts, Department of Environmental Protection	■ Air Quality Certification ■ Water Quality Certification
U.S. Fish and Wildlife Service	■ Endangered Species Coordination
Construction Related Permits or Approvals	
Environmental Protection Agency	■ National Pollution Discharge Elimination System, Stormwater Discharge (Construction Activity)
Massachusetts Department of Environmental Protection, Division of Air Quality; Massachusetts Department of Labor and Industries; and US Environmental Protection Agency	■ Notice Concerning Commencement of Construction or Demolition
Massachusetts Natural Heritage and Endangered Species Program	■ Conservation and Management Permit
City of Boston, Conservation Commission	■ Order of Conditions

1 Not all these permits or approvals may be required.

2 The Massachusetts Historical Commission has concurred that the Preferred Alternative will have no adverse effect on significant historic properties. See Appendix H for the MHC letter to the FAA, dated December 21, 1999

8.7 Proposed Section 61 Findings

The following section outlines a draft Section 61 Finding for the Airside Improvements Planning Project.

DRAFT RESOLUTION AND VOTE OF MASSPORT BOARD IN COMPLIANCE WITH M.G.L. C.30, SECTION 61

WHEREAS, the Authority has been engaged in long-term planning activities to ensure that flight operations at Boston-Logan International Airport ("Logan") are conducted as safely and efficiently as possible in terms of on-time performance and in a manner consistent with established environmental impact policies and goals, and

WHEREAS, in the context of this planning process the Authority has identified a range of alternatives for achieving these results, including specific improvements to the airfield component of Logan, and

WHEREAS, pursuant to the National Environmental Policy Act ("NEPA") and Massachusetts Environmental Policy Act ("MEPA") and related regulations and other requirements, the Authority has been engaged in an environmental review process to examine a number of aspects of the various alternatives under review, including without limitation, purpose and need, analysis of the current and projected flight delay problem, role of the regional airport system and other transportation alternatives in meeting current and forecast passenger demand, affected environment, environmental consequences, environmental justice, and environmental mitigation, and

WHEREAS, the environmental review process under MEPA commenced with the filing of an Environmental Notification Form ("ENF") on July 31, 1995 which was the subject of a formal scoping process, including a public scoping session on September 23, 1995, which process in turn led to the issuance of a Certificate by the Secretary of the Executive Office of Environmental Affairs ("EOEA") defining the scope of the Airside Project Draft Environmental Impact Report ("Draft EIR"), and

WHEREAS, the Airside Project Draft EIR was filed on February 1, 1999, which document included the designation of a Preferred Alternative consisting of the following components: unidirectional Runway 14/32; Centerfield Taxiway; extension of Taxiway Delta; realignment of Taxiway November; improvements to the southwest corner taxiway system; and reduction in approach minimums on Runways 22L, 27, 15R and 33L (which component is an initiative of the Federal Aviation Administration), and

WHEREAS, the Draft EIR was the subject of an extended public comment period, including public hearings on Wednesday, April 7, 1999 at the State Transportation

Building in Boston and Thursday, April 8, 1999 at the Holiday Inn in East Boston, which resulted in the issuance of a certificate from the Secretary of EOEA dated May 7, 1999, in which said Secretary determined that the Draft EIR adequately and properly complied with MEPA and with its implementing regulations and specified certain additional analytic work, including additional mitigation measures and responses to substantive comments, to be included in the Final Environmental Impact Report ("Final EIR"), and

WHEREAS, the Authority filed the Final EIR on [March 15], 2001 and on [DATE] the Secretary of EOEA issued a certificate determining…[TO BE INSERTED]...;

NOW THEREFORE BE IT RESOLVED AND VOTED:

A. The Authority hereby finds that: (a) the environmental impacts associated with the Airside Improvements Project, EOEA No. 10458, and selection and implementation of the Preferred Alternative, are properly and adequately described and evaluated in the ENF, Draft EIR and Final EIR and the description of such environmental impacts set forth in said documents is adopted as a specific finding herein, and (b) by implementing the mitigation measures set forth in the Final EIR (and summarized in this resolution), as authorized and directed by this resolution, all feasible means and measures will be taken to avoid or minimize the description of any environmental impacts as determined by this resolution.

B. The Authority hereby further finds and determines that the improvements constituting the Preferred Alternative as set forth in the Draft EIR and Final EIR will enhance the operation of Logan by improving safety conditions and on-time performance of aircraft and will provide related environmental benefits.

C. The Authority hereby makes the additional findings set forth below in accordance with M.G.L. c.30, Section 61:

IMPLEMENTATION OF MITIGATION MEASURES

The Authority hereby adopts the following environmental mitigation, which measures are set forth in Chapter 8 and other applicable provisions of the Final EIR, and hereby authorizes and directs the Executive Director to implement such measures.

1.0 Runway 14/32 Unidirectional Limitation

Runway 14/32 will be operated as a unidirectional runway to accommodate over-water flight operations only, i.e., arrival operations in an east-to -west direction to the

Runway 32 approach end and departure operations from a west-to-east direction from the Runway 14 departure end. Construction specifications will require that lighting, marking and instrumentation components of Runway 14/32 be done consistent with the above-described unidirectional limitations. No parallel or other type of taxiway facility will be constructed to allow departures from an east-to-west direction from the 32 end. The Authority will, if requested, enter into an appropriate contract with an appropriate governmental body and/or representative community group(s) to provide rights to enforce the intended unidirectional restriction of Runway 14/32.

2.0 Regional Transportation Policy - Regional Airport Network

The Authority is engaged in promoting increased utilization of regional airports and other travel modes to provide relief to Logan Airport. As an independent authority that owns and operates Logan and Hanscom Field, as well as the Tobin Bridge and many properties in the Port of Boston, and has operational responsibility for Worcester Regional Airport, the Authority is just one of many agencies that influence regional transportation policy. With regard to aviation, the Authority's primary responsibilities are the provision, operation and maintenance of airport infrastructure at Logan and Hanscom Field, and the operation of Worcester Regional Airport.

The Authority supports a regional transportation policy to improve the efficient use of the region's transportation infrastructure by expanding use of the regional airports and other transportation modes, where appropriate. To achieve these goals, the Authority is committed to cooperative transportation planning and is actively working with a broad array of transportation agencies and concerned parties to ensure an integrated, multi-modal regional transportation network. The Authority has undertaken several initiatives to advance the role of regional airports in accommodating a greater share of the region's air travel demand. The Authority is also an active participant in several interagency transportation planning forums pertaining to alternative intercity travel modes.

The Authority's efforts in connection with this Regional Transportation Policy will include:

2.1 Worcester Regional Airport

The Authority will continue to exercise operational control over Worcester Regional Airport, continue to work to attract new air service and develop and implement a marketing campaign targeted to travelers and airlines to provide awareness of Worcester Regional Airport and enhance its utilization within its primary service area.

2.2 Cooperative Regional Transportation Planning Initiatives

The Authority will:

- Maintain an aviation information database and distribute quarterly reports that track aviation trends at all of the regional airports to parties interested in promoting regional airport services;

- Compile and issue periodic statistical summaries of passenger levels, aircraft operation counts and airline schedule data at the major New England regional airports;

- Prepare an Annual Report summarizing regional airport trends and service developments;

- Participate in meetings of other regional and state aviation organizations, including the Massachusetts Aeronautics Commission and transportation summit meetings organized by the New England governors;

- Continue to cooperate with the Federal Aviation Administration and directors of other regional airports to undertake and complete a *New England Airports System Study* to evaluate the performance of the regional airports since the completion of the *1995 Regional Airport Air Passenger Service Study*; reevaluate airport market areas and capture rates; evaluate the potential for international, charter and cargo services at the regional airports; evaluate capacity issues at the regional airports; and consider the development of high occupancy vehicle/ground transportation and rail alternatives to improve access to the regional airports;

- Continue to encourage various transportation initiatives (e.g., commuter rail, rail or other links between regional airports) by relevant agencies or other governmental bodies through Transportation Bond Bill or other legislative initiatives that may be required to implement an improved effective regional transportation system;

- Continue to assist in the development of a comprehensive rail plan for New England, including the designation of high rail corridors;

- Continue to support inter-city rail planning through membership in the Metropolitan Planning Organization (MPO).

3.0 Residential Sound Insulation

The construction and operation of Runway 14/32 will significantly reduce the most severely noise-impacted populations within the 70 and 75 dB DNL contours in East Boston, Winthrop and Revere. This reduction results from a distribution of flights more consistent with the Preferential Runway Advisory System (PRAS) goals. However, the change in distribution levels resulting from the availability of Runway 14/32 will also increase the population within the future 65 dB DNL contours in comparison to the No Action alternative and in comparison to 1998 conditions. This increase will be mitigated by providing sound insulation to

affected residences (located in Chelsea, East Boston and South Boston) that fall within the 65 dB DNL contour for the Preferred Alternative as defined in the 1999 29M Low Fleet scenario (see Final EIR, Table 8.5-1). The number of dwelling units that will be sound insulated are within the new airport wide contours reflecting the conditions of the 29M Low Fleet DNL contour and the sound insulation program will be structured to meet FAA funding requirements. Relevant FAA general sound insulation program funding requirements do not provide sound insulation benefits for buildings that do not meet applicable building codes. However, in order to ensure that all residents of buildings who would otherwise be eligible for sound insulation do not lose eligibility because of building code considerations, funds will be provided, through special Project mitigation commitments from the FAA, to allow for building code upgrades to be made on individual homes to the extent that building code upgrades are necessary to allow the sound insulation work to be completed. To further ensure that all eligible residences are included within the sound insulation program, the specific identity of residences will be determined based upon a detailed block-by-block analysis to be performed during implementation.

4.0 Tenant Relocation Assistance

As described in the Draft EIR and Final EIR, the construction of Runway 14/32 will require the demolition of existing Cargo Building 60 and Cargo Building 61. The current tenant, pursuant to plans independent of the Airside Improvement Project, will vacate Building 61. In connection with its acquisition of Building 60 the Authority will provide relocation assistance to building tenants as required by applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, as amended, Part 24 of 49 CFR and M.G.L. Chapter 79A and implementing regulations. Relocation resources will be made available to all eligible business relocatees without discrimination.

5.0 Vegetation and Wetlands

All construction associated with the Preferred Alternative is confined to upland portions of the Logan airfield. There will be no loss of wetlands as a result of the implementation of the Preferred Alternative. During construction, sediment and erosion controls will be implemented within the 100-foot buffer zone of the coastal bank. All areas disturbed by construction will be stabilized with vegetation common to the airfield once re-grading is completed.

6.0 Wildlife

Construction of the Centerfield Taxiway and the Taxiway Delta extension will result in the conversion of approximately 37 acres of grassland to paved surface, thereby eliminating this area as habitat for the upland sandpiper. In coordination with the Massachusetts Natural Heritage and Endangered Species Program (NHESP), the

Authority will develop a mitigation plan to address this impact and that will comprise the following elements:

- Alteration of existing airfield grassland mowing procedures prior to the spring arrival of the upland sandpiper to encourage occupation of other areas of the airfield rather than the construction area.

- Implementation of a pre-construction and an on-going pre-mowing upland sandpiper reconnaissance program to ensure that no individual birds remain in the area.

- Off-site habitat enhancement.

Enhancement of bird habitat at Logan is not feasible due to the significant potential of increased aviation hazards. As part of the Conservation and Management Permit process under the Massachusetts Endangered Species Act (MESA), the Authority in coordination with the NHESP will develop a comprehensive onsite and offsite mitigation program to provide a "net benefit to the local population" of upland sandpipers. The offsite mitigation is expected to involve funding from the Authority for a grassland restoration/habitat enhancement program at Camp Edwards on Cape Cod. Under this program, the Authority will provide funds to the Massachusetts National Guard (MNG) for restoration of the former upland sandpiper habitat. A Memorandum of Understanding (MOU) between the Authority and MNG to ensure effective implementation of the program is anticipated. In the event that such a program at Camp Edwards is not available, an appropriate alternative program acceptable to the NHESP will be developed and implemented.

7.0 Water Resources

Construction of the Runway 14/32 and Taxiway components of the Preferred Alternative will result in a slight increase (3.8 percent) in peak runoff to tidal waters. Peak discharges will be minimized through the use of grassed swales and infiltration of runoff. No long-term impacts to water quality are anticipated. The existing stormwater drainage system will be reconfigured slightly to accommodate runoff from the runway and taxiway improvements. A low-flow water quality treatment structure will be incorporated into the existing system to handle the first flush runoff from portions of the airfield, if feasible. Sediment and erosion controls will be installed and maintained during all portions of construction to minimize adverse impacts. Construction will be phased to minimize the extent of bare soil at any one time. All new runway and taxiway construction within areas subject to DEP's Stormwater Management Policy will be consistent with applicable policies and performance standards.

8.0 Soils

Disposal of soils excavated for runway and taxiway construction will be completed in compliance with the Massachusetts Contingency Plan (MCP), 310 CMR 40.0000, and will be conducted in a manner consistent with the Authority's Soil Management Plan developed for the Logan modernization projects.

9.0 General Construction Mitigation

Appropriate measures to enhance safety and mitigate traffic, air quality, and noise impacts will be incorporated into the contract documents and specifications governing the activities of contractors and subcontractors constructing all construction elements of the Preferred Alternative.

All construction activity associated with the Preferred Alternative will comply with FAA Advisory Circular 150/5370-2C, Operation Safety on Airports During Construction. In addition, the Authority will utilize a number of mandatory construction mitigation procedures for all construction contractors. The Authority will employ a team of on-site resident engineers and inspectors to monitor all construction activities related to the Preferred Alternative, including the following management practices:

- Full coordination with the CA/T Project, and with all relevant agencies including the FAA, MBTA, Massachusetts Turnpike Authority, Massachusetts DEP, Massachusetts Coastal Zone Management (CZM), Massachusetts Water Resources Authority (MWRA), City of Boston, Boston Water and Sewer Commission (BWSC), and utility companies, as appropriate.

- Preparation of detailed pre-construction plans for traffic maintenance, construction specifications for contractors, and coordinated scheduling of all construction activities (as well as the other measures noted in the ground transportation sections above).

Construction mitigation measures in a number of categories are described below.

9.1 Construction Traffic Operations

- Construction vehicles will be required to use State highways or Logan roadways, including the Ted Williams Tunnel, except when seeking access to local businesses. A clause to this effect will be inserted in all construction contracts relating to the construction components of the Preferred Alternative.

- Truck routes for Logan projects that minimize impacts on the local communities will be established. Construction vehicles would be restricted from using Neptune Road, Maverick Street, and Porter Street in East Boston. Designated truck routes will be specified in all construction contracts.

- Construction employee parking spaces will not be permitted on the construction site nor will provisions be made for them elsewhere on-airport with the exception of a small number of spaces for supervisory personnel. It is

expected that construction workers will access the airport via public transportation or via shuttle buses from off-airport parking areas.

- Police details will be employed at appropriate locations on the airport to manage traffic and ensure public safety.

9.2 Construction Air Quality

- The Authority will require contractors to retrofit their heavy construction equipment with advanced pollution control devices during construction in accordance with DEP's Clean Air Construction Initiative. Contractor-owned equipment such as front-end loaders, backhoes, cranes and excavators will be retrofitted with oxidation catalysts. This device filters out and breaks down hydrocarbons, particulate matter and carbon dioxide associated with diesel emissions.

- During the construction process a regular program of street sweeping will minimize dust from construction vehicle movements on airport roads.

- Fugitive dust also will be controlled with water spray as needed during demolition and construction; no chemical soil stabilizers will be used.

- All trucks hauling demolition materials and excavate from the site will be covered and their wheels will be washed prior to leaving the construction site.

9.3 Construction Noise

General construction noise will be limited using techniques such as:

- Use of: (1) concrete crushers or pavement saws for building demolition or similar construction activity; (2) local power grid to reduce the use of generators, to the extent practicable and feasible.

- Attaching (1) intake and exhaust mufflers, shields, or shrouds; (2) noise-deadening material to inside of hoppers, conveyor transfer points, or chutes.

- Maintaining equipment to ensure peak performance.

- Limiting (1) the numbers and duration of equipment idling on the site; (2) the use of annunciators or public address system; (3) the use of air or gasoline-driven hand tools.

- Configuring, to the extent feasible, the construction site in a manner that keeps loud equipment and activities as far as possible from noise-sensitive locations.

When construction is scheduled during the nighttime hours and near community sensitive areas (e.g., East Boston and Winthrop) the following noise mitigation measures will be employed.

- The use of backup alarms for all pieces of equipment will be prohibited, to the extent appropriate. The Contractor will be required to provide additional laborers to assure that equipment backup safely and comply with OSHA regulations.

- Trucks delivering bituminous concrete or other materials will be prohibited from slamming their tailgates to clean out truck beds after dumping.

- During paving operations, the contractors will be required to turn off their vibratory compactors prior to exiting off the newly place pavement and onto the old existing pavement.

Further noise control options will be evaluated during the ongoing project design to define their effectiveness and feasibility. Appropriate operational specifications and performance standards will be incorporated into the construction contract documents.

10.0 Preferential Runway Advisory System (PRAS) Monitoring and Reporting

The Authority will develop and implement a PRAS Monitoring System and will implement a new distribution system for reports. The Massport Quarterly Noise Reports will be expanded to include a number of new reports, and the distribution list will be expanded to include interested parties, including the Logan Citizens Advisory Committee. In addition, the annual reports on runway utilization, dwell and persistence will also be included as part of the Environmental Status and Planning Report (ESPR) (formerly GEIR) filings made with the Executive Office of Environmental Affairs. Over the longer-term, the Authority will work with the FAA to design additional reports that could help enhance the attainment of PRAS.

11.0 Peak Period Monitoring System and Exemption Program

The Authority will establish and maintain a monitoring system that will; (i) provide advance indication of when airline overscheduling is likely to become a significant contributing factor to aircraft arrival and departure delays at Logan, and (ii) identify the portion of the day during which an overscheduling condition would likely occur. As initially conceived, the key components of this system will be as follows:

- Projections of Logan flight activity will be developed on a semi-annual basis. These projections will be prepared 4 to 6 months in advance and will represent estimates of flight levels by hour for the upcoming seasonal schedule period. Projections will be based on the most recent activity levels of Logan, historic seasonality patterns, and advance flight schedules submitted by air carriers to the Official Airline Guide (OAG). The projections will also reflect non-scheduled activity including charter and general aviation.

- Logan's average runway capacity under Visual Flight Rule (VFR) conditions will be evaluated as required.

- Delays due to overscheduling will be quantified though an analysis that simulates the projected flight schedules against Logan's VFR capacity. Delays

will be estimated by hour to permit designation of a specific peak period when overscheduling conditions are likely to cause significant delays.

When projected delays due to air carrier overscheduling are estimated to reach or exceed an average level of 15 minutes per flight (which standard is based on FAA criteria) over a period of three or more consecutive hours in a day, the Authority will take the following curative actions:

Phase 1: Voluntary Schedule Adjustments. The Authority will meet individually with air carriers that exhibit significant levels of flight activity during the identified peak period. These carriers will be informed that Peak Period Pricing will be invoked for the relevant period unless flight schedules are reduced below key threshold levels. If voluntary schedule adjustments occur at levels that will avoid the original overscheduling situation, no further action will be necessary.

Phase 2: Regulatory Action. If voluntary schedule adjustments do not eliminate the overscheduling situation, the Authority will take the necessary steps consistent with applicable legal requirements to put into effect a surcharge applied to flights arriving and departing Logan during identified peak hours. A properly structured exemption program, consistent with federal law requirements, will also be put into effect. The purpose of the exemption program is to prevent affected communities from losing access to the national airport system.

The Authority will continue to monitor flight schedules at Logan on a periodic basis and make adjustments to the peak period as warranted by future schedule changes. The Authority will make adjustments to the monitoring system and related action plan as may be appropriate to address any overscheduling situation that may arise.

12.0 Hushkitted Aircraft

As air carriers and cargo operators phased out their remaining Stage 2 aircraft (gross weight >75,000 pounds) in compliance with federal statutory requirements, some opted to retrofit their older Stage 2 aircraft with “hushkits”, designed to reduce noise levels to meet the Part 36 Stage 3 noise limits. Other carriers and operators replaced their Stage 2 aircraft with new technology Stage 3 airplanes. Air carriers and cargo operators at Logan Airport have done both. Substituting new full Stage 3 aircraft results in more significant noise abatement benefits.

The reduction in noise exposure that will be experienced as fleet changes continue depends heavily on how many hushkitted aircraft remain in operation over the next few years. While not related to Airside Project impacts, the Authority will continue to work with air carriers to encourage the use of full Stage 3 aircraft in place of hushkitted equipment.

List of Preparers

List of Preparers

The Logan Airside improvements Planning Project *Draft Environmental impact Statement/Draft Environmental Impact Report*, is a joint effort of the Federal Aviation Administration (FAA) and the Massachusetts Port Authority (Massport). Technical analyses and documents were prepared by a team of consultants. The entities involved, as well as the personnel their individual areas of responsibility, are listed below:

Federal Aviation Administration, New England Region

Vincent Scarano – Manager, Airports Division
John Silva - Manager, Environmental Programs, Airports Division
Ralph Nicosia-Rusin - Capacity Program Manager, Airports Divisions

Massachusetts Port Authority

Thomas Kinton -Director of Aviation
Betty Desrosiers - Director of Aviation Planning and Development
Flavio Leo - Manager of Aviation Planning
Stewart Dalzell- Deputy Director of Aviation Planning and Development
(as of September 2000)

Simat, Helliesen & Eichner — Project Management, Purpose and Need, Regional Alternatives, Peak Period Pricing

Deborah Meehan - President / Project Manager
David Hollander - Director / Peak Period Pricing, Purpose and Need
Beverly Jones - Director / Regional Alternatives, Purpose and Need
John Brandt – Senior Consultant
Andrew Goldman - Consultant

Flight Transportation Associates, Inc. - Operational Analysis, Delay Modeling

William C. Hoffman-President

Harris Miller Miller & Hanson, Inc. - Noise impact analysis

Robert L. Miller – Sr. Vice President and Supervisory Consultant
Robert C. Mentzer – Consultant
Ashish Maru -- Consultant
Dana R. Turchi – GIS Specialist

URS, Inc. - Air quality analysis

Mike Steer, P.E. - Principal Consultant
Michael A. Kenney, QEP, CHMM- Air Quality Assessment Coordinator
Kristin Marshall – Air Quality Specialist

Frederic R. Harris, Inc. - Land Use, Cultural Resources, Cumulative Impacts

Joanne Haracz, AICP - Environmental Planner
Maureen Cavanaugh – Senior Planner
Crystal Johnson - Environmental Planner
Cathal Ridge - Planner
Marilyn Palmer - Planner

Jason M. Cortell and Associates, Inc. – Natural Resources

Stewart Dalzell – Natural Resources Task Manager / Public Involvement
Carlton L. Noyes – Water Quality / Soils Management
Marshall W. Dennis – Vegetation and Wildlife Impact Assessment / Mitigation Planning

Edwards & Kelcey – Runway/Taxiway Layout, Computer Simulations

William Richardson - Principal Airport Planner
Kenneth Scarborough - Airport Planner
Edmund Dawes, P.E. - Principal Airport Engineer
James Falvey, P.E. - Airport Engineer
Nils Gonzalez, P.E. - Airport Engineer

Vanasse Hangen Brustlin, Inc. – Document Production

Carol Lurie – Senior Associate, Airport Services
Frank Bracaglia – Senior Project Manager
Marla Engel – Senior Planner
Jill Cohen – Planner
Scott Schilt – Planner
Karen Berchtoldt – Planner
Kristin Hychka – Environmental Scientist
Terri Courtemarche – Graphic Designer
Fani Nicheva – Graphic Designer
Daniel Boudreau – Cartographer / GIS Specialist

Reviewers List

This Supplemental Draft EIS / Final EIR is being distributed to federal, state and city agencies and to the interested parties on the following pages. This list includes those entities that the Federal Aviation Administration's Airport Environmental Handbook (Order 5050.4A) and the Massachusetts Environmental Policy Act regulations (301 CMR 11.00) require as part of the review of the document, including representatives of government agencies and community groups concerned with airport activities. Copies of this report are available at the following public libraries: Bedford Public Library; Boston Public Library, Main Branch, Charlestown Branch, Dedham Public Library; Dudley Branch (Roxbury), East Boston Branch, Jamaica Plain Branch, Orient Heights Branch, South Boston Branch, Tremont Street; Watson Park Library in Braintree; Brookline Main Library; Chelsea Public Library; Cohasett Public Library; Concord Public Library; Edgartown Free Public Library; Everett Public Library; Hingham Public Library; Hull Public Library; Cary Memorial Library; Lincoln Public Library; Malden Public Library; Medford Public Library; Melrose Public Library; Milton Public Library, Main Branch; Nahant Public Library; Nantucket Atheneum; Quincy Public Library, Thomas Crane Branch; Provincetown Public Library; Revere Public Library; Somerville Central Library; Weymouth Public Library; and Winthrop Public Library. Additional copes of this report are available from Massport, 205 South, Suite 205 / 206S, Logan Office Center, One Harborside Drive, East Boston, MA 02128, telephone (617) 568-3500. The following persons may be contacted for additional information concerning this document:

Acronyms

AC	Advisory Circular
ACHP	Advisory Council on Historic Preservation
ADT	Average daily traffic
ADG	Airplane Design Group
ADSIM	Airfield Delay Simulation Model
AIP	Airport Improvement Program
Airside Project	Logan Airside Improvements Planning Project
AIRS	Aerometric Information Retrieval System
AITC	Airport Intermodal Transit Connector
ALP	Airport Layout Plan
ALPA	Air Line Pilots Association
ALS	Approach Lighting System
ANCA	Airport Noise and Capacity Act
APO	FAA Office of Aviation Policy and Plans
ARC	Airside Review Committee
ARP	Airport Reference Point
ARTS	Automated Radar Terminal System
As	arsenic
ASQP	Airline Service Quality Performance
ATA	Air Transport Association
ATC	Air Traffic Control
ATCR	Air Traffic Consumer Reports
ATCT	air traffic control tower
ATIS	Automatic Terminal Information Service
APUs	Auxiliary Power Units
BMPs	Best Management Practices
BVFR	Basic Visual Flight Rules
BWSC	Boston Water and Sewer Commission
CAA	Clean Air Act
CAC	Community Advisory Committee
CA/T	Central Artery/Tunnel Project
Cd	cadmium
CEP	Capacity Enhancement Plan
CEQ	Council on Environmental Quality

CERL	U.S. Army Construction Engineering Research Laboratory
CFR	Code of Federal Regulations
CM	construction management consulting firm
CMR	Code of Massachusetts Regulations
CNI	Cumulative Noise Index
CO	carbon monoxide
CODAS	FAA's Consolidated Operations and Delay Analysis System
Cr	chromium
CRS	Computerized Reservation Systems
cy	cubic yards
dB	decibel
dBA	A-weighted decibel
DELAYS	(a delay simulation model)
DELAYSIM	(a delay simulation model)
DEP	Department of Environmental Protection
DH	decision height
DNL	Day-Night Sound Level
DOT	Department of Transportation
Draft EIS/EIR	Draft Environmental Impact Statement/ Environmental Impact Report
EA	Environmental Assessment
EAS	Essential Air Service
EDMS	Emissions and Dispersion Modeling System
EDR	Environmental Data Report
EIR	Environmental Impact Report
EIS	Environmental Impact Statement
ENF	Environmental Notification Form
EOEA	Executive Office of Environmental Affairs
EOTC	Executive Office of Transportation and Construction
EPA	Environmental Protection Agency
EPNL	Effective Perceived Noise Level
ESPR	Environmental Status & Planning Report
ETMS	FAA's Enhanced Traffic Management System
FAA	Federal Aviation Administration
FAR	Federal Aviation Regulation
FEIR (Final EIR)	Final Environmental Impact Report
FHWA	Federal Highway Administration
FIS	Federal Inspection Services

FLAPS	Flexible Airport Simulation Model
FONSI	Finding of No Significant Impact
FRA	Federal Railroad Administration
FSEIR	Final Supplemental Environmental Impact Report
GA	General Aviation
GEIR	Generic Environmental Impact Report
GIS	Geographic Information System
GSE	ground service equipment
GNTM	Ground Noise Taxi Model
Hg	mercury
HOV	high occupancy vehicle
Hz	hertz
IFR	Instrument Flight Rules
ILS	Instrument Landing System
IMC	Instrument Meteorological Conditions
INM	Integrated Noise Model
INS	Immigration and Naturalization Service
LDA	Landing Distance Available
LDMS	Logan Dispersion Modeling System
Leq	equivalent sound level
LeqN	night equivalent sound level
Lmax	Maximum Sound Level
Logan	Boston-Logan International Airport
LOGIC	Logan Growth and Impact Control
MAC	Massachusetts Aeronautics Commission
MA DEP	Massachusetts Department of Environmental Protection
MAMA	Massachusetts Airport Managers Association
MA NHESP	Massachusetts Natural Heritage & Endangered Species Program
MASHPO	Massachusetts State Historic Preservation Office
MassHighway	Massachusetts Highway Department
Massport	Massachusetts Port Authority
MBTA	Massachusetts Bay Transportation Authority
MCP	Massachusetts Contingency Plan (310 CMR 40.0000)
MEPA	Massachusetts Environmental Policy Act
MESA	Massachusetts Endangered Species Act
MGL	Massachusetts General Law
MHC	Massachusetts Historical Commission

MLS	Manual Landing Systems
MNG	Massachusetts National Guard
MPO	Metropolitan Planning Organization
MOA	Memorandum of Agreement
MOU	Memorandum of Understanding
MTA	Massachusetts Turnpike Authority
MWRA	Massachusetts Water Resources Authority
NAAQS	National Ambient Air Quality Standards
NAVAID	navigational aid
NEC	New England Council
NECIP	Northeast Corridor Improvement Project
NEPA	National Environmental Policy Act
NHESP	Natural Heritage and Endangered Species Program
NHPA	National Historic Preservation Act of 1968
NMS	Noise Monitoring Site
NO_2	nitrogen dioxide
NO_x	oxides of nitrogen
NOI	Notice of Intent
NPDES	National Pollution Discharge Elimination System
NPS	National Park Service
NTSB	National Transportation Safety Board
O_3	ozone
O&M	Operations and Maintenance
OAG	Official Airline Guide
OFA	Object Free Area
OFZ	Obstacle Free Zone
OPSNET	FAA Air Traffic Operations Network
PACE	Program for Airfield Capacity Efficiency (1998)
Pb	lead
PCB	polychlorinated biphenyls
PDA	Planned Development Area
PFCs	Passenger Facility Charges
$PM_{2.5}$	particulate matter less than 2.5 microns in size
PM_{10}	particulate matter less than 10 microns in size
PPI	PRAS Performance Index
ppm	parts per million
PPP	Peak Period Pricing
PRAS	Preferential Runway Advisory System
Preferred Alternative	Alternative 1A (includes all actions except Peak Period Pricing)

RCRA	Resource Conservation and Recovery Act
RDSIM	Runway Delay Simulation Model
REIL	Runway End Identifier Lights
ROD	Record of Decision
ROFA	Runway Object Free Area
RON	remain over-night
RPZ	Runway Protection Zone
RSA	Runway Safety Area
RVR	Runway Visual Range
SAR	Strategic Assessment Report
SDEIS	Supplemental Draft Environmental Impact Statement
SDEIS Panel	Supplemental Draft EIS Panel
Supplemental DEIS/ FEIR	Supplemental Draft Environmental Impact Statement / Final Environmental Impact Report
SID	Standard Instrument Departure
SIMMOD	Simulation Model (FAA)
SIP	State Implementation Plan
SMGCS	Surface Management Guidance & Control System
SO_2	sulfur dioxide
STIP	Statewide Transportation Improvement Program
TA	Time Above (a specified noise level)
TAAM	Total Airspace and Airport Modeler
TERP	Terminal En Route Procedures
TIP	Transportation Improvement Plan
TOFA	Taxiway Object Free Area
TPH	Total Petroleum Hydrocarbons
TRB	Transportation Research Board
TSA	Taxiway Safety Area
TSS	Total suspended solids
USPS	United States Postal Service
VAPS	Visual Approach Procedures
VFR	Visual Flight Rules
VOC	volatile organic compounds
29M	29 million passengers
29M Low Fleet	29 Million annual air passenger Low Fleet
37.5M	37.5 million passengers
37.5M High Fleet	37.5 Million annual air passenger High Fleet

Re: Analytic Tasks for Logan Airside Improvement Project Supplemental Draft EIS

Dear Betty and Deborah:

I have enclosed a document entitled "Additional Analysis for the Logan Airside SDEIS" which constitutes a description of the additional analysis that should be incorporated into the Supplemental Draft Environmental Impact Statement ("SDEIS") for the Logan Airside Improvement Project. The SDEIS will be the next formal submission made by FAA in respect to FAA's ongoing review of the Logan Airside Improvement Project under the National Environmental Protection Act and related FAA requirements. (FAA is also the project proponent with respect to certain elements of the Preferred Alternative – i.e., the reduction in approach minimums on runways 22L, 27, 15R and 33L). The enclosed document has been finalized by FAA following discussion of earlier drafts with the SDEIS Panel, described below, and is intended as our directive concerning specific items identified as a result of the SDEIS Panel process that are to be included in the SDEIS.

The SDEIS was required as a result of a determination by Administrator Jane Garvey in January 2000. As part of this determination, Administrator Garvey asked for the formation of a special panel (the "SDEIS Panel") consisting of six members, three of whom would be appointed by Governor Cellucci (Lieutentant Governor Jane Swift, Mr. Richard Egan and Mr. John Butler) and three of whom would be appointed by Mayor Menino (State Representative Byron Rushing,

Ms. Mary Ellen Welsh, and Mr. Raymond Tye). The SDEIS Panel met over a ten month period (March – December 2000). In my judgement, the process was substantive and involved review of analysis produced by Massport and the FAA with respect to the Project EIS process to date, presentations by various technical experts, comments from members of the public attending the SDEIS Panel meetings, and the active participation through numerous insightful inquiries, suggestions and comments from the individual SDEIS Panel members. Both FAA and the SDEIS Panel members also had the benefit of consultation with a special independent expert to the Panel hired by FAA in response to a Panel request. All of this work provided FAA with context for developing the enclosed list of analytic tasks and other materials to be included in the SDEIS. The panel process also assisted in identifying tasks that may be included in a subsequent new Regional Airports System Study.

In addition to providing the analysis and other materials specified in the enclosed document, a copy of the minutes of the various SDEIS Panel meetings as well as a copy of this letter and enclosed document must be a part of the SDEIS submission. We believe that it would be beneficial for SDEIS reviewers to have available to them the record of the SDEIS Panel process and the results of that process which appear in the form of the enclosed list of specific analytic tasks.

On behalf of Administrator Jane Garvey and all of us at FAA who had the benefit of their participation, I want to reiterate our gratitude for the extraordinary dedication and assistance of the individual SDEIS Panel members throughout the process. Their contribution to FAA's deliberations and to the public review process for this Project is evidenced by the substantive content of the list of analytic tasks developed as a result of their input.

Sincerely,

Vincent A. Scarano
Manager
Airports Division

cc: Administrator Jane Garvey
Members of the SDEIS Panel
Mr. James Muldoon
Ms. Suzanne Orenstein

ADDITIONAL ANALYSES FOR THE LOGAN AIRSIDE SUPPLEMENTAL DRAFT EIS

Task	Task Description

1.0 Is a 5,000 ft Runway 14/32 effective given the expected use of regional jets in the future fleet mix? (To be performed by FAA consultant)

1.1 Verify and confirm previous survey of airlines and manufacturers to determine minimum arriving /takeoff distances for regional jet aircraft.

1.2 Research regional jet aircraft usage and runway length requirements at other airports.

1.3 Review forecast mix of regional jet aircraft types at Logan.

1.4 Develop estimate of probable regional jet utilization of a 5,000 ft. Runway 14/32.

2.0 Expand Regionalization analysis contained in Interim Supplemental Draft EIS ("Brown Book")

2.1 Discuss proposed New England Regional Aviation System Study and proposed work scope.

2.2 Update to reflect the current status of traffic and services at the regional airports, Amtrak's Acela service, and ground access projects.

2.3 Add historical context and on-going nature of regionalization efforts.

3.0 Expand analysis of peak period pricing.

3.1 Review changes in airline scheduling activity at Logan and assess how and why the demand profile has flattened over time.

3.1.1 Determine which new airline/markets have contributed to changes in the demand profile.

3.1.2 Assess whether the flattened profile or a more peaked profile is likely to occur in the new future fleet (2015 Modified 37.5M RJ fleet).

3.2 Discuss the design of a Peak Period Pricing program that would impact regional jet scheduling practices at Logan.

3.2.1 Base analysis on modified 2015 Modified 37.5M RJ fleet, using an updated demand profile and a small community exemption program.

3.2.2 Discuss the economic cost of peak period pricing to the consumer.

3.2.3 Discuss the uniqueness of Cape Air and the communities that it serves.

3.3 Identify known, comparable demand management strategies that are in use or have been proposed by other airports.

4.0 What impact does the 2015 Modified 37.5M RJ fleet mix have on delay reduction benefits and environmental impacts?

4.1 Develop 2015 fleet mix and demand profile assuming 37.5M passengers and increased RJ utilization.

4.2 Assess the impacts of the new fleet on delays, runway utilization, noise contours and noise-exposed populations for Alternatives 1, 1A, 2, 3 and 4.

4.3 Assess the impacts of the new fleet on ground noise and air quality for Alternatives 1/1A and 4.

4.4 Perform delay sensitivity analysis using varying RJ utilization factor for Runway 14/32.

5.0 Broaden discussion of national delays to put Logan delays into context.

5.1 Assess Logan's relative national delay ranking if Runway 14/32 was available in 1998.

5.2 Discuss how delays at Logan affect the national air transportation system.

5.3 Discuss measures FAA is pursuing to reduce delays nation-wide.

6.0 Analyze potential wind/weather use restrictions on Runway 14/32 and their impact on delay reduction, runway utilization, and PRAS achievement.

6.1 For the 2015 Modified 37.5M RJ fleet, analyze and compare delay levels and runway utilization patterns for: (1) No Action, (2) Action [a.] As Modeled with PRAS and [b.] with wind/weather restrictions on the usage of Runway 14/32.

6.2 Determine impact of potential restrictions on utilization of Runways 27 and 33 for departures, PRAS achievement, and ability to reduce population exposed to the highest noise levels

7.0 Present enhanced flight track graphics on the same GIS base map used for the Brown Book noise contours, show individual tracks, extend into the South Shore, and show altitudes.

8.0 Incorporate a summary of existing analyses from the Draft EIS for Alternatives 1, 2, and 3 into the SDEIS in addition to the No Action (Alt. 4) and Preferred Alternative (Alt. 1A).

9.0 Analyze the potential for proposed infrastructure improvements (Runway 14/32 and taxiway improvements) and Peak Period Pricing to induce demand for Logan Airport.

10.0 Compare current measured noise levels from monitors in residential neighborhoods to modeled results from the Integrated Noise Model (INM).

11.0 Address the following specific issues for which clarification has been requested:

11.1 Provide data and discussion on predicted change in activity by runway end, including daytime and nighttime distribution.

11.2 Clarify discussion of proposed Centerfield Taxiway and its impact on the number of aircraft queuing on that taxiway and other taxiways waiting to depart.

11.3 Respond to written questions submitted by SDEIS Panel member, Mary Ellen Welch

12.0 Produce a school year/school day 65 dB contour for the Preferred Alternative for the 29M Low fleet. Research school day operating hours in relevant surrounding communities to determine the appropriate hours for the analysis.

SDEIS Panel Minutes

Boston Logan International Airport
Supplemental Draft EIS (SDEIS) Panel

Minutes
December 4, 2000

I. Participants: All Panelists were present.

II. Discussion

Opening Remarks

- The meeting opened at 4:08 PM. The facilitator noted that this was the final scheduled meeting for the Panel.
- Ms. Orenstein reviewed the agenda and asked for comments on the minutes for the November 13 and 28 meetings. The minutes were finalized and accepted for distribution and posting on the web site. The minutes for this final meeting will be distributed to panelists for comment, and will be finalized after any comments are received.

Overview of Logan Airport's Role in Future Coordinated Regional Airport System

- Mr. Scarano introduced Virginia Buckingham, Executive Director and CEO of Massport, who discussed the vision for Logan Airport's future with the Panel. She noted that Logan's primary focus for the future will be on long-haul and international service. She noted measures Logan is implementing to prepare for that role, including:
  - Renovation of the international Terminal E;
  - Replacement of Terminal A;
  - New west parking garage and elevated walkways to all terminals;
  - Improved ground access, including greater use of HOVs, a fourth remote location for Logan Express in the north for the Rte.1/95/128 area, remote baggage check-in, HOV improvements to Cape Cod, a new Blue Line Station, and Logan Dart service to South Station, which expects to serve 60,000 riders this year.
- Ms. Buckingham discussed Logan's role in promoting a regional airport system, noting that Logan will serve only 30% of the new passengers in the future. She noted that Massport manages two other airports in the region, Worcester and Hanscom, and spoke about plans for improving the success at Worcester. Worcester has the capacity to serve 800,000 passengers. Its highest passenger year was 1989, when it served about 380,000 passengers. In 1999, Worcester served around 50,000 passengers, but with improvements in service, this year it has already served 100,000 fliers. Regarding Hanscom, she noted that it would continue as the region's largest general aviation airport, with some niche commercial service.
- Ms. Buckingham noted that Massport hopes that the new Acela train service will be able to take 40% of Logan's New York shuttle traffic.
- Ms. Buckingham noted that the New England governors were addressing air transportation as part of the second transportation conference coming up next week. Lt. Governor Swift distributed invitations to the summit to all Panelists.

- Question: Mr. Tye asked what percent of Logan's traffic is considered short-haul.
- Answer: About one-third.

- Question: Lt. Governor Swift asked how Ms. Buckingham viewed Massport's role in achieving regional airport growth and multi-modalism.
- Answer: Ms. Buckingham spoke about creating incentives for greater regional airport use and for promoting the growth of other airports in discussions with airlines.

- Question: Lt. Governor Swift asked how Massport was addressing issues of reliability at Worcester Airport.
- Answer: Cancellation levels for Worcester weather have been low. However, there is a perception that Worcester is not reliable, which needs to be corrected. Massport is considering whether technology improvements at Worcester will improve reliability.

- Question: Mr. Tye asked why a new runway is needed if Logan wants to be an international, long-haul airport.
- Answer: Delays in NW winds affect all passengers, and need to be eliminated. Also, Logan will always need smaller planes to feed connecting passengers to the long-haul flights.

- Comment: Ms. Welch noted that a true regional approach should mean fewer small aircraft, and with Acela service and the number of days NW winds are a problem, the new runway is not needed. Ms. Welch noted that FAA and Massport are taking a giant step in working towards true regionalization, but suggested that demand management strategies should be tried and evaluated prior to building a runway.

- Question: Rep. Rushing asked about other types of operations that could be reduced at Logan.
- Answer: Massport is trying to move charter flights to other airports, but is being challenged on the grounds that it would be discriminatory. They are also looking at moving cargo operations, but since about 60% of cargo arrives in passenger planes, Logan will always need some cargo moving capability. Massport is also looking at changes in general aviation facilities that may decrease the desirability of flying into Logan for general aviation, and they are discussing changes in Fed Ex and UPS operations.

- Comment: Ms. Welch asked if anything could be done to improve bottlenecks on Routes 1 and 1A north. She also noted that a new truck route recently funded by state transportation officials would improve truck traffic.

- Ms. Buckingham thanked the Panelists for their work on the SDEIS and noted the need to get a resolution on the runway issue. Mr. Scarano and the Panelists thanked Ms. Buckingham for her presentation.

Review of List of Potential Additional Analyses

The Panel reviewed the revised list of Potential Additional Analyses and made the following suggestions. (*Denotes an item on which significant disagreement was expressed. +Denotes an item on which there was agreement among panelists.)

Item Suggestion

1 -Include info re: New Haven where regional jets are requiring 7000 ft. RW

2 -Add Amtrak, buslines, and highway improvements to second bullet
-Incorporate forecasts and info from master plans for Manchester and T.F. Green
+Update Brown Book Chapter 2 re: regionalization

3 -Analyze 2010 modified 34 million passengers as part of A, bullet 2
-Analyze 2010 fleet for 34 million passengers as part B, bullet 1
+Add uniqueness of Cape Air and communities it serves to B, bullet 3
+For section C, look at all known, comparable, demand management strategies in use or proposed at other airports

4 No suggestions

5 -Restore the deleted task of estimating the cost of total delays, not just Logan-caused delays
-Determine and state Logan's relative rankings nationally among airports for delays if the runway is built. Assumptions, parameters, factors held constant to make this analysis feasible would need to be determined (e.g. assume other airports do not improve). Determine this for each alternative for one year, five years, and ten years out.
-Discuss how delays at Logan affect the national air transportation system, and how delays in the national system affect Logan

6 *Add: PRAS should not be factored into analysis until it is updated

7 No suggestions

8 *Analysis should consider feasibility and changes that would be required to implement change in first come-first serve. (Other view was to drop this item)

9 No suggestions

10 *Determine maximum growth capacity and limitations at Logan, including looking at current growth rate and determining and stating in document the capacity of the airport in operations per year

11 -Change wording to "Compare current measured noise levels..."

12 -In bullet one, consider eliminating the study of the operational capacity of a single runway configuration

13 -Add to bullet 3: "queuing on that taxiway and other taxiways..."
-Discuss whether FAA standards will be waived for the safety areas - bullet 1

14 +Confirm that hours for school-day noise contour are from 7 AM to 4 PM

Additional Item: Reconsider geographic component of EJ analysis.

Mr. Rushing requested that the Panel be provided with the revised list of additional analyses. Ms. Orenstein noted that it would be provided.

Schedule for Moving Forward

- Mr. Egan asked that the schedule for moving forward with the SDEIS be outlined. The following schedule was projected.

Studies	Through mid-February
SDEIS out to public and Panel	First week in March
Public Comment Period	Through April 15
MEPA Certificate	April 22 (seven days after close of public comment)
FEIS	May 30

- The question of whether the Panel should meet at some point to review the draft SDEIS was not resolved. Some felt the disagreements would not be resolved, so it was not necessary to meet. Other felt that meeting might help to narrow some of the disagreements among Panel members. It was left that the Panel might be invited by the FAA to meet and review either the draft or the public comments on the draft, but that it was not certain that this would happen.

Panel Input on Regional Air Study and Other Intermodal Planning Efforts

- Mr. Scarano talked about the new Regional airport study, noting that it would take 12-18 months to complete and would reflect a rapidly changing environment.
- The Panel provided the following suggestions.
  - Recognize the need for on-going, always-making-progress effort.
  - Speculate about unconstrained possibilities, to be as comprehensive and forward thinking as possible.
  - Identify information from the previous plan (1995) that was most useful in predicting and reacting to growth, (e.g. route analysis) and place a priority on updating that information.
  - Consider ground access factors, including Routes 1 and 1A north near airport.

- Include all New England airports, perhaps in two categories of closer in to Boston and a broader range of secondary airports, like Portland, Bradley, New Haven, etc. Pease Airport should definitely be part of the analysis.
- Look at improving train routes throughout New England, not just New York to Boston.
- Factor in how noise abatement projects for all airports and train routes could be used to reduce resistance from neighbors.
- Look at and propose the level of leadership that will be required to do both air and intermodal coordination on an interstate level.
- Look at barriers that will prevent coordination and how to address them.

III. Public Comment

Dan Wolf of Cape Air said that Cape Cod communities want environmental and roadway impacts looked at if air service to the Cape was going to be curtailed through the implementation of Peak Period Pricing. He also asked whether the road system to Logan could accommodate a move toward more high-occupancy aircraft.

John Marcy of Winthrop addressed the Panel about air quality impacts from the airport. He noted that Chapter 6 of the SDEIS should reflect issues with particulate emissions, as noted in the preliminary Winthrop health effects survey.

Anastasia Lyman, Co-chair of the CAC, asked if the noise contours in the SDEIS would be the same as in the Brown Book. The response was that SDEIS would include the 1998 contour base case, with a new 2015 contour. Ms. Lyman also thanked the FAA for opening up the Panel process to the CAC and the public.

IV. Closing Comments

- Mr. Scarano thanked the Panel members for their hard work and said he believed that FAA's expectations were met. He noted that the Panel had accomplished all it was asked to do, and had been very understanding of the need for additional meetings and discussion. He said he was aware that some of the public's expectations may not have been met, but he noted that he was satisfied with the efforts to include the views of the CAC, the EPA, and experts from outside the Massport consultant pool. He noted FAA's response to some of the public comments in the hiring of Jim Muldoon as the independent technical expert, and in the opening of the meeting to observers and their comments. He thanked all involved for their cooperation and contributions. (The outline of Mr. Scarano's comments is attached.)
- Mr. Butler thanked Mr. Scarano and Ms. Orenstein for helping to achieve a balanced discussion process.

V. The meeting adjourned at 6:50 PM.

Boston Logan International Airport
Supplemental Draft EIS (SDEIS) Panel

Minutes
November 28, 2000

I. Participants: All Panelists were present.

II. Discussion

Opening Remarks

- The meeting convene at 4:07 PM.
- Ms. Orenstein noted that this meeting was the second to the last in this Phase of the Panel's work. The final meeting for this Phase is Monday, December 4.
- The agenda for this meeting was reviewed, with the addition of a representative from Winthrop's Health Action Committee to the section on Air Quality.
- Mr. Scarano apologized for the delay in circulating the minutes from November 13. He asked that Panelists review them prior to the next meeting.

Presentation and Discussion of Air Quality Impacts from the Airside Improvements Project

- Mike Kenney from URS, the consultant who conducted the air quality analysis for the Draft EIS, presented an overview of the AQ findings.
  - He explained that his study covered emission levels of criteria pollutants, dispersion modeling of the emissions, and comparisons with the allowable levels. The study found no expected violations and the lowest emission levels with Alternatives 1 and 1A. One factor in the results is that as airport equipment and operations become more efficient, pollutant emissions will be reduced.
- Mr. Tye asked what pollution might one expect without the airside improvements. Mr. Kenney explained that the results would be the same. He further explained in response to a request for clarification from Ms. Welch that while the airport is a proportionally greater contributor of pollutants to those who live next to it, it is still small by comparison with other nearby sources of pollution such as roadways and toll booths.
- Ms. Welch stated that odor and soot are obvious problems for airport abutters, and it was hard to believe that the airport was not raising the levels of those pollutants for its neighbors and that that these pollutants would not increase with increasing operations at the airport. Mr. Kenney noted that for most studies around airports it has been impossible to separate out airport emissions from all other urban air pollution sources. When Ms. Welch asked about the soot study conducted at Logan several years ago, Mr. Kenney noted that it was unable to link soot to specific sources.
- Mr. Egan noted that the proposed improvements at Logan were designed to increase efficiency and that the fewest expected emissions were from Alternative 1/1A, which includes the runway.
- Mr. Brian Dumser, a member of Winthrop's Health Action Committee, presented the findings of a study of Winthrop residents in two Winthrop neighborhoods that varied in their proximity to the airport. The study showed that there were twice as many

diagnosed cases of asthma and respiratory disease in the neighborhood closest to the airport. Mr. Dumser presented the results as the communities effort to begin to understand air quality impacts, noting that further, more rigorous study is needed and may be undertaken by the MA Dept. of Public Health.

- Mr. Egan asked Mr. Dumser if he would welcome measures that would decrease pollution from the airport. Mr. Dumser said he would.
- Mr. Nicosia-Rusin asked whether, if one accepts that there is an increased rate of respiratory disease resulting from higher airport emissions, would it be reasonable to expect the incidence of disease to decline as aircraft pollutants decrease. Mr. Dumser responded that it is unclear what elements of aircraft pollution are tied to disease, and specifically questioned the role of particulate emissions.
- Ms. Meehan asked if Mr. Dumser would agree that if the preferred alternative reduced pollution and there was no induced demand increasing it, that the airside improvements could be desirable in terms of health concerns. Mr. Dumser did not feel that there was sufficient data about any of the projects to state any view conclusively.
- Ms. Welch noted that a health study is needed, citing the proximity of the Court Road neighborhood to the sources of pollution. She noted that better data on the health impacts of the airport on surrounding neighborhoods are needed. Other panelists agreed that health effects data were needed, but some noted that health effects studies should not be tied to the airside improvements project, because it was an issue for the airport as a whole.

<u>Overview and Discussion of Mitigation Proposals in the DEIS</u>

- Deborah Meehan of S, H & E presented an overview of the mitigation proposed in the DEIS. She noted the following proposed elements of the mitigation package.
  - Commitment to unidirectionality as a noise abatement factor,
  - Sound insulation of the impacted area, particularly in Chelsea,
  - Moving the upland sandpiper off-site, including habitat enhancement,
  - Increased PRAS monitoring and reporting,
  - A Peak Period pricing monitoring program,
  - Over-water nighttime preference as part of PRAS,
  - Voluntary reductions in the use of hush-kitted aircraft, and
  - Promotion of regional airports and alternative transportation modes.
- Several Panelists asked questions about the soundproofing program. Mr. Silva explained that accomplishing the soundproofing as part of this project would result in quicker action for the affected homes than if they were part of Logan's on-going program. He also noted that FAA has agreed to bring homes up to code if necessary to accomplish the soundproofing, which is an unusual step. Mr. Egan asked what the average cost of soundproofing would be per house, and Mr. Silva noted it could be about $30,000 each. Mr. Egan noted that the total cost would be over $30 million.
- Other mitigation ideas proposed by the panelists included:
  - Is a "harbor mouth" approach a potential mitigation for RW 14-32 traffic? Also for increased approaches on RW33?

- Could a sharper left turn off RW 22, keeping track over water, help mitigate noise? Feasibility of this? [Mr. Butler noted this would put planes on directly intersecting paths.]
- What RW 14-32 impacts is unidirectionality mitigating?
- Need to reassess PRAS with community. Need to add today's airport procedures to system.
- Are there any schools that should be added within the 65 school year, school day DNL?

- Ms. Welch asked whether PRAS would be reevaluated as part of the Supplemental Analysis or as a mitigation measure. She accepted that this item was part of the mitigation effort.

Outline of Mechanisms for Unidirectionality Commitments

- Richard Littieri of Ropes and Gray described three levels of potential commitments to unidirectionality.
  - *Operational commitments* include the Hyatt Hotel as an obstruction, the striping and lighting of the runway for unidirectional use, the lack of a taxiway for bi-directional use, and establishment of ATC procedures for unidirectionality only.
  - *Administrative or Regulatory commitments* would result from the fact that the project would only be permitted for unidirectional use.
  - *Contractual commitments* could be accomplished by an enforceable contract with the communities or by a negotiated agreement that the current injunction would continue to be in force for all operations other than the unidirectional operations.
- Ms. Welch asked how often Records of Decision have been overturned or violated. FAA responded that the EIS process would have to be repeated if the ROD were changed.
- Mr. Egan asked if all Panelists were satisfied that unidirectionality could be guaranteed. Ms. Welch responded that she has seen other agreements unfulfilled, and was not yet convinced on this issue.
- Lt. Governor Swift asked if commitments on all three levels would help make the communities more confident in the promise of unidirectionality. Ms. Welch noted that the communities would have to consider and discuss that.
- Mr. Rushing asked what impacts are being mitigated by unidirectionality. He suggested that this question be addressed in the Supplemental Analysis.

Review of Revised List of Additional Analysis Items for SDEIS

The Panel reviewed the revised list of potential items for analysis in the SDEIS; this version incorporated the comments from the Panel's discussion at the last meeting.

- Lt. Governor Swift suggested clarifying the section on PPP to incorporate special circumstances for unique communities and airlines.
- Mr. Rushing asked that the list be left open for discussion and additions until the Dec. 4 meeting, as had been previously agreed. Lt. Governor Swift asked for advance notice of any suggested additions so that Panelists could be prepared to address them, given that the Dec. 4 meeting was the last meeting. Panelists agreed to provide advance notice of any proposed items if at all possible.

III. Public Comment

Dan Wolf, President of Cape Air, said that a peak period pricing program would have the biggest impact on the user, Cape Air, with the least impact on delays. He mentioned that it could put 500 people out of work. He concluded that it was not a good technical solution, but that it may be discussed as a political solution for addressing runway opponents concerns. He asked that other avenues be sought for the political purpose.

Blossom Hoag of the Sierra Club asked about how the RW14-32 operations would accommodate missed approaches, given the obstruction of the hotel. She also spoke in favor of improving rail links to the north, and noted her dissatisfaction with the fact that substantive Panel discussions were cut off prematurely.

At the end of the public comment session, Ms. Welch responded that Cape Air is a special situation for the Peak Period Pricing option, and that the CAC feels that there should be exemptions for Cape Air in any PPP proposal.

IV. Planning for Next Meeting

Mr. Scarano suggested that the next meeting be devoted to doing a final review of the List of Items for Additional Analysis in the SDEIS, and also that he would appreciate Panelist input on the proposed Regional Air Study and other regional intermodal transportation initiatives. The Panelists agreed to this agenda. Mr. Scarano also distributed copies of an article from Boston Magazine about the Accela train service.

Mr. Tye asked that as part of the discussion of regionalizing air transportation, Massport present its vision for Logan's future. Ms. Meehan noted that Chapter 2 of the Brown Book presents quite a bit of information about Logan's role in the regional system, but that she would like to hear how that Chapter could be improved. The Panel accepted the idea of a presentation from Massport.

The next meeting will be on December 4, 4:00 to 7:00 PM, at the Volpe Transportation Center, 55 Broadway, Cambridge.

The meeting adjourned at 7:00 PM.

Boston Logan International Airport
Supplemental Draft EIS (SDEIS) Panel

Minutes
November 13, 2000

I. Agenda (See attached)

II. Participation: Mr. Tye was unable to attend.

III. Discussion

Opening Remarks and Review of Agenda and Minutes

- The Panel convened at 3:31 pm.
- Ms. Orenstein said that the major topic of the meeting would be a review of FAA's working draft of additional work for the SDEIS.
- Mr. Scarano noted that a letter from EPA, Ms. Welch's questions, and a letter from Cape Air were distributed to the Panel. He also noted that the Working Draft of areas of potential additional analysis, distributed to the Panel, represent FAA's thinking to date and that the additional analysis doesn't appear to change the schedule for publication of the SDEIS.
- The Panel introduced themselves for the benefit of the public.
- Ms. Orenstein asked for comments to the minutes of 10/10 and 10/12. There were none and the Panel accepted them with the understanding that they would be published on the web site.

Introduction to List of Items for SDEIS Analysis

- Mr. Scarano referred to those additional analysis areas where work had already begun.
  - Mr. Muldoon, consultant to the Panel, updated the Panel on Item 1 of the List of Additional Analyses (analysis of regional jet use of RW 14-32), saying that turbo-prop forecasts were down and regional jet forecasts were up.
  - Mr. Egan clarified that 3 of the 4 Regional Jet aircraft could use the proposed 5,000-foot runway. Mr. Muldoon added that actually all four could technically use it but the commitment was not as certain for the Challenger aircraft.
  - Mr. Hollander of SH&E stated that runway length vs. aircraft use would be assessed. He added that there were benefits even if three of the four aircraft could use the runway. Mr. Butler reiterated this.
  - Ms. Welch said that even if the aircraft were capable, some carriers might decide not to use the runway. She asked if a comparison would be made to other airports, including an analysis of the effect of the hotel as an obstacle. Mr. Butler responded that FAA would consider the appropriate missed approach altitude for Runway 32.
  - Mr. Scarano mentioned that analysis of the runway safety area would reflect Ms. Welch's concerns with landings on Runway 32.
  - Lt. Gov. Swift said that the analysis should look at the impact on safety from the proposed runway.

- Mr. Scarano addressed Item 2, "regionalization", particularly additional work on a separate study to look at other airports and transportation modes and their capability to reduce traffic at Logan. He said that a Scope of Work should be ready by early spring. Lt. Gov. Swift added that this effort needs to be undertaken within the context of regional study work already conducted.
  - Ms. Welch asked if telecommunications would be included. Mr. Scarano responded that it would.
  - Mr. Egan wanted assurance that this additional work would not delay the SDEIS. Mr. Scarano responded that since the regional study might take two years, there was no intent to hold up processing the SDEIS.
  - Lt. Gov. Swift said that the study would have value as a tool for the future.
  - Mr. Welch said it was important to get a regional plan in place prior to completing the SDEIS.
  - Lt. Gov. Swift said that there needs to be a commitment to regional planning as part of the EIS process.
  - Mr. Nicosia-Rusin said that the rationale for the runway is contained within the SDEIS and is not affected by the results of "regionalization".
  - Rep. Rushing requested an analysis of why "regionalization" is not a substitute for the new runway.
- Mr. Hollander began a discussion of Item 3, demand profile. Lt. Gov. Swift suggested it be combined with Item 4, peak-period pricing. There was agreement to combine all demand management sections.
  - Mr. Hollander said that a broader peak-period pricing program over a greater number of hours would be assessed.
  - Ms. Welch wanted to know if LaGuardia and San Francisco proposals to deal with congestion would be addressed. Mr. Hollander responded that they would.
  - Mr. Hollander spoke about price elasticity with relation to demand.
  - Lt. Gov. Swift wanted to know how peak-period pricing would affect other major markets and would like to see a benefit-cost analysis of its impact on consumers.
  - Discussion continued over designing a peak-period price that would be feasible.
- Mr. Hollander continued with Item 5, an assessment of the 2015 Regional Jet fleet and its affect on delay reduction and environmental impact, and Item 6, a broader discussion of delays to include the interface of other airports.
  - Rep. Rushing asked what position Logan would place in delays after a Runway 14-32 was constructed. Mr. Egan and Mr. Butler questioned the value of studying this, explaining that all airports could improve, thereby maintaining the same relative rankings.
  - Ms. Welch said that the cost of delays included all delays and not necessarily those associated with the runway. Mr. Hollander clarified that the delay data was only related to Logan delays, not delays from other airports.
- Regarding Item 7, potential restriction of the use of Runway 14-32, Ms. Welch asked if Runway 15L-33R could be encouraged more.
  - Mr. Hollander, Mr. Scarano, and Mr. Davies of the Tower spoke about the interrelationship of both of the 15-33 runways.

- Regarding Item 8, demand management at other airports, Mr. Hollander discussed LaGuardia and recent efforts for a temporary lottery followed by a more permanent pricing program.
  - Ms. Welch spoke about the need to consider peak-period pricing sequentially--implement it first, then assess its effect. Discussion followed on the degree to which this was already included in the Brown Book.
- Mr. Scarano mentioned Item 9, a better graphics depiction of noise.
- Mr. Hollander went over Item 10, modifying first-come, first-serve air traffic control procedures to see what affect it would have. After some discussion among Panel members, Mr. Rushing argued that if it had a benefit, an explanation of what it would take to implement it should be included.
  - Mr. Scarano added that the measure might not have an effect in delay reduction.
  - Mr. Butler said that safety of the measure would preclude it and objected to including it in the List of Additional Analyses.
  - Mr. Egan felt it could be logically dismissed, once the effect was known, because of its impracticality.
- There was agreement on Item 11, the need to combine the original DEIS with the SDEIS and produce one document. Mr. Silva mentioned that this would make processing simpler by avoiding the need to republish the original DEIS.
- Regarding Item 12, potential induced demand of the proposed improvements, Ms. Welch said it was important to know if the improvements would create new demand.
  - Rep. Rushing said that if additional demand were anticipated it would be important to know the extent that this would have on making a decision to go forward with the Runway now.
  - Mr. Scarano responded that the benefit of the runway in delay reduction would always be present.
- Mr. Hollander addressed Item 13, measured versus modeled noise, saying that recent information comparing the two would be included in the SDEIS.
- Regarding Item 14, the level of operations that would not produce delay benefits, Mr. Egan and others noted the impracticality of achieving this if it were studied. Lt. Gov. Swift recommended that, once a level of operations was determined, we look at when it occurred historically and other benchmarks of activity such as airline prices, etc.
- Regarding Item 15, which includes additional discussion of the centerfield taxiway, there was expression of the need to clarify the runway and centerfield taxiway layout.
- Mr. Rushing mentioned an additional area, the comparison of Environmental Justice populations. Mr. Scarano noted that this was a subject under discussion with EPA. Mr. Silva added that it might be precluded from additional analysis as a result of ongoing discussion.

<u>FAA Response to Questions Raised at the Panel Meeting of 10/12/00 Related to Reductions in Landing Minimums</u>

- Following a 15-minute break, Mr. Davies addressed questions from the 10/12/00 meeting about reductions in minimums. He explained the descent profile to an airport, specific examples for Logan's runways, and the benefits of reduced minimums. The benefits include having the missed approach point closer to the runway and more distant from the community, fewer missed approaches, having runways other than 4R to conduct

approaches in poor visibility, and better compliance with the Preferential Runway Advisory System.

- As part of discussion of Mr. Davies presentation, Mr. Silva explained the history of the FAA agreement with Massport to first do an EIS before reducing minimums. Mr. Nicosia-Rusin added that normally reductions in minimums would require only a Categorical Exclusion (from the need to provide an environmental assessment).
- Ms. Welch addressed community concern with safety as aircraft descend lower.

IV. Observer Comments

- Ms. Anastasia Lyman of the Community Advisory Committee referred to a recent EPA letter on the SDEIS process and discussed induced demand, the cost-of-delay data that needs to be compared with the cost of environmental impact, and a question about the degree of design that has occurred. Mr. Nicosia-Rusin explained that design has not progressed to any substantial detail.
- Mr. Dan Wolf of Cape Air spoke to peak-period pricing. He said that Cape Air does not have the option to go to larger aircraft because of the need to adjust to seasonal demand. He also doubted that peak-period pricing would be effective for very long. Finally, he said that Cape Air presently fills in the holes in runway availability, and is not a factor in Logan delays.
- Dave Kresge of Chelsea did not believe that FAA should be determining whom aircraft would be flying over. He also objected to the delay statistics and no representation on the Panel from Chelsea.

V. Planning for Meeting of November 28, 2000

- Ms. Orenstein went over potential agenda items for the next meeting.
- Mr. Rushing asked if this evening's comments could be integrated into the List of Additional Analyses prior to the next meeting (11/27).
- There was a brief discussion of environmental mitigation. Rep. Rushing reiterated his concern about Environmental Justice and the population comparisons.
- Ms. Orenstein went over the agenda for the next meeting on 11/28/00: air quality, mitigation, unidirectional runway commitment, and a review of a revised list of additional work analysis.

VI. The meeting adjourned at 6:00 PM.

Boston Logan International Airport
Supplemental Draft EIS (SDEIS) Panel

Minutes
October 10, 2000

I. Agenda (See attached)

II. Participants: Mr. Butler was unable to attend.

III. Discussion

Opening Remarks, Review of Minutes, Updates

- Ms. Orenstein opened the meeting at 3:08 p.m., going over the agenda: noise and environmental justice for this meeting and a continuation of Environmental Justice and Preferential Runway Advisory System (PRAS) at the 10/12 meeting (In addition to a trip to the Tower to observe PRAS).
- Mr. Scarano said FAA has been looking into 3 issues: use of Runway 14-32 by the regional jet (RJ) fleet, impact of the RJ s on fleet mix, and the regional airport system.
- Lt. Gov. Swift suggested that FAA begin to revise the Brown Book without waiting for all Panel deliberations to be completed.
- Mr. Scarano said all additional work items, as determined by the FAA, will be presented at the 11/13 meeting.
- Mr. Egan asked how long the process would go after Nov. 13th. Mr. Scarano responded that the Brown Book would be revised in about 3 months, followed by a 45-day comment period on the SDEIS, then at least 30 days before o FEIS and another 30 days to produce a record of decision. Lt. Gov. Swift again suggested that the initial 3-month analytic period might be shortened if FAA directs the consultant to begin some work now.
- Mr. Rushing said he was interested in the format for additional work. He added that he believed there might be agreement on many of the items for additional study. Mr. Scarano said he would make the list available for the Nov.13th meeting.
- In response to a question from Mr. Tye, Mr. Scarano explained that, in addition to the SDEIS, an additional regional systems study will be done. The SDEIS will rely on systems planning work already accomplished. Mr. Scarano also said the SDEIS would go further than the Brown Book in this area.
- Ms. Meehan suggested that we stop making presentations. She needs to know more of what the Panel thinks. Mr. Tye responded that the presentations are part of education. Ms. Orenstein said that additional emphasis would be placed on Panel discussion time.
- Comments on the minutes of the 9/27/00 meeting: Mr. Egan noted Mr. Odoni's response to an observer comment. Mr. Odoni felt he was misquoted.

Noise Questions

- Mr. Miller began a discussion of noise questions which came out of the previous meeting (see agenda and handout). He went over factors affecting average day-night

sound levels (maximum sound level, duration, the number of events, and how many occur between 10pm and 7am). He went over additional metrics: maximum sound level, sound exposure level, equivalent sound level, and time above threshold sound levels. He said that they were used in the EIS.

- In response to what other airports have done to address impacts, Mr. Miller discussed flight corridors, preferential runway use, noise barriers and run-up enclosures, sound insulation of homes, noise abatement departure procedures, and voluntary and mandatory access restrictions.
- In response to the specific noise impacts of the centerfield taxiway, Mr. Miller explained that over-flight noise was dominant but that modest improvements in taxiway noise were achievable by relocating some taxiing aircraft further from the corners of the airport. Ms. Welch noted that Taxiway N would still be used. In response to a question from Lt. Gov. Swift, Mr. Miller explained a worst-propagation scenario that shows noise reduction with the centerfield taxiway. Ms. Welch argued against DNL by stating that averaging events does not relate to what the community experiences. Mr. Nicosia-Rusin explained that presently all aircraft taxiing to the ends of runway 22R and 22L use Taxiway N and approximately ½ of these would be able to use a centerfield taxiway further from the community. Ms Welch said this would enable greater taxiway capacity. Mr. Egan said this issue had already been addressed and that while Ms. Welch might not like the metric Mr. Miller was saying that noise would go down. Ms. Welch brought up that additional capacity would result in additional operations and noise. Mr. Silva explained that the availability of additional taxiway capacity would not likely cause additional operations. The airlines would not schedule additional operations because of the availability of the centerfield taxiway. Discussion continued among panel members on this point.
- Reference the question of simultaneous approaches to Runways 32 and 33, Mr. Miller said it can't be done, but that the noise exposure would be the same regardless. Mr. Silva added that two simultaneous operations would have less exposure than sequential operations.
- Reference the question of specific elements of noise analysis for Runway 14-32, Mr. Miller explained that tracks over the south shore and additional operations from Runway 27 would not exceed FAA's guidelines of significant noise levels. Ms. Welch suggested a different explanation by stating that a 3 dBA increase is a doubling of the sound energy. Mr. Miller agreed that was taken into account in the noise analysis.
- Ms. Welch asked about other studies on the relationship between noise and impact on people, mentioning a study about impact on fetuses. Mr. Miller responded that such health studies have been inconclusive.
- Mr. Miller concluded that at more distant sites such as Hull, none of the alternatives would produce significant noise levels (65 DNL or above).

<u>Observer Comments</u>

- Ms. Lyman asked whether the centerfield taxiway would bring aircraft ground noise closer to Winthrop. Mr. Davis answered not necessarily. Ms. Lyman also asked about increases in noise from increased operations on Runway 33.

- Mr. D'Amico said that the centerfield taxiway would bring aircraft ground noise closer to Winthrop. He also noted that at one time Massport decided not to go ahead with the centerfield taxiway north of Runway 33.

The meeting concluded at 5:58 p.m.

Boston Logan International Airport
Supplemental Draft EIS (SDEIS) Panel

Draft Minutes
September 27, 2000

I. Agenda (See attached)

II. Participants: All panelists were present.

III. Discussion

Opening Remarks, Review of Minutes, Updates

- The meeting opened with a review of the agenda. The facilitator noted that the focus of this meeting would be on concluding the discussions of delays at Logan, and beginning the discussion of environmental impacts.
- Mr. Scarano updated the Panel on several items.
  - He communicated Mr. Egan's questions about accelerating the Panel process to FAA Director, Jane Garvey, and received no indication from her of any need to accelerate the process. He also requested information for the panel about how the national summit on delay relates to the Panel's work, and is awaiting a briefing paper which he will distribute.
  - Mr. Scarano clarified that the summary of comments and responses to the DEIS sections on noise that were distributed to Panel members had not been updated since the Panel began meeting, and therefore should not be expected to include any ideas discussed in Panel meetings.
  - Mr. Scarano distributed copies of letters regarding Shuttle America's proposal to serve Laguardia Airport from Hanscom. He noted that Mr. Rushing had requested copies of these letters, and that he was providing them to all panelists, as required by the groundrules. In the discussion of the topic of these letters, consultation with the State Historic Preservation Office (SHPO), a question arose about the consultation with SHPO on the Airside Improvements Project. John Silva from FAA stated that section 106 coordination was completed as part of the Airside DEIS. Information was provided to the SHPO, including noise contours and identification of historic properties, and the SHPO had found no historic resources were unduly impacted. Mr.Rushing mentioned that Congressman Moakley had requested a review of this finding in a letter to the FAA.
- The minutes for Sept. 6 were reviewed. A typo was corrected, as was a statement of Mr. Scarano regarding a regional airport coordination meeting. Mr. Rushing asked a follow up question to an item in the minutes about Mr. Scarano's attending the Sept. 18 CAC meeting. He asked if there were minutes from that meeting. During Public Comment, Anastasia Lyman, Chair of the CAC, noted that there are minutes that could be made available to the Panel after they are finalized.
- Ms. Welch submitted a list of written questions and concerns from several community groups. She also noted that community members from the town of Winthrop have asked

the Panel to delay finalizing the SDEIS until after completion of a study of health effects from the airport on citizens of several neighborhoods in Winthrop. Mr. Scarano noted that the information about the study could be submitted during the public comment process on the SDEIS. Mr. Egan spoke against the need for the Panel process to be delayed. Mr. Tye noted the need to have as much information as possible for the ROD, and Mr. Rushing noted that if the information would improve the SDEIS, it should be reviewed. The duration and completion date of the study are not known, but will be researched prior to the next meeting.

Congestion at Logan Airport and Potential Remedies: Presentation by Professor Amedeo Odoni.

- Amedeo R. Odoni, T. Wilson Professor of Aeronautics and Astronautics at MIT, provided a briefing to the panelists based on his academic experience, nationally and internationally, evaluating delay and delay reduction at airports. He noted that there is no question that Logan is a seriously congested airport, with about 100,000 hours of delays per year. This level of delay represents about $150,000,000 in costs to airlines and $150,000,000 in costs to travelers. He outlined three potential solutions for the short term: Runway 14/32, peak-period pricing, and improvements in Air Traffic Control (ATC). He agreed with the delay reduction projections for the runway presented by other consultants, but noted that projected delay reduction benefits may be reduced by the switch from turboprops to regional jets. He further explained that for peak-period pricing, a small number of flights could result in a large decrease in delays. For example, a one per cent reduction in flights, could reduce delays by 7%. He noted that demand by non-jets at Logan has been reduced from 1993 to 1998, and that the 1998 demand is flatter over the day. He suggested analyzing the reasons for this change as part of the SDEIS analysis. Regarding ATC improvements, Dr. Odoni felt that their benefit at Logan is minimal – perhaps 5-10% - because of the complex geometry at the airport. He summarized his suggestions for further analysis as follows:
    - Determine if regional jets will use Runway 14/32 in sufficient numbers to achieve projected delay reductions.
    - Define and examine how 14/32 could be used in IFR, in addition to the VFR conditions.
    - Analyze why hourly demand changed between 1993 and 1998 to obtain information that may help design effective demand management.
- Professor Odoni noted that the medium and long-term solution for Logan airport is to develop a coordinated regional airport system because demand will eventually continue to exceed capacity, even with improvements. This will require Logan to make some tough decisions about its most appropriate role in the regional system. He reiterated that the outlook for Logan to improve in delays is bleak, and that the eventual capacity is probably limited to 550,000-580,000 operations. With current operations at 510,000, there is only room for 10% growth, which is much lower than the amount by which unconstrained demand might increase over the next 10-20 years.
- Lt. Governor Swift asked Professor Odoni what he saw as the major constraints to the development of a regional system. He responded that institutional constraints are the most obvious, and that the airports need to feel they have stakes in each others'

success. He further noted that the process of making choices about Logan's specific role in the regional system would also be difficult.

- Mr. Rushing asked what the definition of capacity is at Logan. Mr. Odoni said it is the number of operations per hour that can be accommodated without violating ATC constraints. For Logan this is 120 operations per hour in VFR.
- Mr. Tye asked how many hours of the 100,000 hours of delay are perceived by the consumer. Professor Odoni noted that Logan is perceived as a very unreliable airport by consumers, whether or not they perceive the hours of delay with each flight.
- Mr. Scarano asked whether and to what extent federal and state laws impede collaborative planning among airports. Professor Odoni said they play a large role. For example, recent federal legislation that says only planes with under 71 passenger can be added to Laguardia makes little sense and goes in the opposite direction to what should be happening there.
- Mr. Scarano asked if there are examples of integrated airport systems elsewhere. The response was that London's three airports are operated in a coordinated manner, and that Amsterdam and Brussels are coordinated. The mechanisms for encouraging coordination do not necessarily have to be regulations; price incentives on gates and fees for passenger use of terminals can also be used to create appropriate incentives.
- Mr. Tye asked if Runway 14/32 would restrain the growth of delays at Logan. Professor Odoni said it would under NW wind VFR conditions, and possibly in IFR conditions. The delay reduction will be temporary, because additional demand will fill in, but that increase in demand would occur anyway and would create worse problems without Runway 14/32.
- Ms. Welch asked about the suggestion to use runways 32 and 33 in parallel in IFR conditions. She suggested that the simultaneous approaches would create more noise, especially when planes approach over land rather than the required over-water approach. Professor Odoni noted that the least environmental impacts are from approaches on runways 33 and 32, if the flights adhere to the flight paths.
- Ms. Welch asked why the changes in the fleet mix to include regional jets might reduce delay reduction benefits from the runway, asking if the difference between what the aircraft manufacturers say is sufficient runway length and what pilots feel is sufficient is a factor. Professor Odoni agreed with this reasoning, noting that pilots may reject the 5000 foot runway, as they have objected to Land and Hold Short procedures.

<u>Overview of Noise Impacts from Airside Improvement Project</u> – Bob Miller, HMMH

- Bob Miller of HMMH presented an overview of the analysis conducted for the DEIS of noise impacts from the Airside Improvement Project. He explained the DNL metric and the use of 65 DNL as an FAA guideline of residential land use compatibility. He described current and past noise rules at Logan, and the soundproofing insulation program. He reviewed the noise contours in the DEIS, noting that fewer people will be exposed to the highest level of noise – 75 and 70 DNL – and that there would be a slight increase in noise within the 65 and 60 DNL. He outlined mitigation measures to address these impacts, including noiseproofing and PRAS monitoring to improve the distribution of the noise across neighborhoods.

- Ms. Welch noted that even at levels lower than 65 DNL, the aircraft noise is irritating and distracting. Mr. Miller noted that 65 DNL is the cut-off for federally funded soundproofing, but it does not mean that those at 64 DNL have no impacts. He further mentioned that EPA has identified 55dB as being of concern, and that studies have found that in 55dB areas, 17% of the population experience annoyance.
- Mr. Tye asked at what dB level conversation would need to stop. The response was around 60-65.
- Ms. Welch noted that assumptions about how often planes fly over water are not borne out in practice. She also noted that if 14/32 is built, flights off of runway 27 will triple, and that needs to be factored into the impact assessment.
- Mr. Rushing asked why there are increases projected in exposed populations. Mr. Miller responded that take-offs and landings will be in different geographic areas with the new runway.
- Lt. Governor Swift noted that it would be useful to provide the Panel with a handout explaining what is included in the metric of DNL. She further noted that delays are irritating, just as airplane noise is, and asked if there was information available about the extent of annoyance caused to consumers by delays.

IV. Public Comment

- John Marcy, from Winthrop and a member of Winthrop's AIR Environment-Health Committee, presented the panelists with a copy of a letter to Jane Garvey explaining the upcoming study of health effects from the airport and requesting that the Panel not be concluded prior to the completion of the study.
- Anastasia Lyman, Chair of the CAC, noted the need for community involvement in the Panel's work, offered copies of the minutes of the recent CAC meeting to panelists, and asked that the Panel and public be provided with a copy of the recent Chicago O'Hare air quality study. She further noted that there is a need for new noise rules at Logan.
- Blossom Hoag asked that Ms. Welch's questions be placed on the web site, and that there be more outreach to the public. She further commented that she is surprised at the limited amount of discussion among the Panelists, and that the process seems to consist mostly of lectures by advocates for the runway.
- Steve Lathrop from Hull reminded the Panel that the south shore is affected by airport operations, and that over-the-water flights often affect Hull. He noted that some flights pass over Hull High School at 1500 feet.
- Mr. Pepper-Eisenberg, of Save Our Heritage, spoke in favor of peak-period pricing as an important part of the solution. He referenced Mr. Odoni's support for it, and also noted Mr. Odoni's statements that the runway is a temporary fix. He questioned why the runway is needed if it will be a short-lived solution. (Professor Odoni responded to this question after the meeting. See his note, attached.)
- Gerry Falbo from Winthrop noted that cumulative effects of additional operations did not correspond to the cumulative noise exposure described by Mr. Miller.

V. Scheduling and Planning for Next Meeting

- The Panel agreed to continue the discussion of noise and environmental justice at the next meeting, which was rescheduled to October 10.
- The Panel scheduled several additional meetings to accommodate its workplan. They are:

  October 10, from 3 to 5 PM
  November 13 from 3:30 to 6:00 PM
  December 4, from 4:00 to 7:00 PM
- The October 12 meeting previously scheduled will be held as a reserve date in case the discussion of October 10 is not completed, and would be held with only four panelists present if it did go forward.
- The December 4 meeting will be focussed on Panel review of a proposed outline for the draft SDEIS, and will be the final meeting before the SDEIS is developed.

VI. The meeting adjourned at 7:05 PM.

Boston Logan International Airport
Supplemental Draft EIS (SDEIS) Panel

Minutes
August 22, 2000

I. Agenda (See attached)

- The Panel convened at 11:15 AM

II. Discussion

Opening Remarks, Review of Minutes, Updates

- Suzanne Orenstein, facilitator, opened the meeting with a review of the agenda, noting that the focus for this meeting was on sources of delays and demand management strategies.
- *Minutes:* The final minutes for the July 13 meeting were distributed. The minutes for the July 26 meeting were revised after Mr. Egan commented that Mr. Davies responses to several questions were more emphatic than noted in the draft minutes. His suggested revisions were accepted by the Panelists.
- *Regional Airport Visits.* It was noted that the Panel had completed visits to Providence and Worcester airports, and was scheduled to visit Hanscom and Manchester on August 28. Handouts from the visits were distributed to those Panelists who did not participate. Mr. Scarano mentioned that Pease airport, a large converted military facility, might be another airport for the Panelists to visit, and offered to arrange a tour on request.
- *National Air Traffic Delay Summit.* Several Panelists noted the national news about airport delays. Mr. Egan distributed articles from *The Boston Globe* and *U.S.A. Today.* He also noted reports of the summit on airport delays convened by Secretary of Transportation, Rodney Slater, on August 21. He particularly noted the identification at the summit of seven choke points in the airport system, one of which is Logan Airport. He asked the FAA to inquire whether national actions on delay would necessitate or benefit from an acceleration of the Panel process. Mr. Tye asked the Chair to ask Administrator Garvey for information from the summit that could help the Panel in its deliberations, particularly whether there is a national plan to deal with the delays, including those in Boston. In response to Mr. Egan's suggestion of a need to accelerate the Panel process, Ms. Welch asked that the Chair also request of the FAA a moratorium on expansion at all New England airports until a regional inter-modal transportation plan, with citizen input, was developed.
- *Independent Technical Consultant.* Mr. Scarano introduced Jim Muldoon, who has been hired as FAA's technical consultant to the Panel. Mr. Scarano noted that Jim had worked as General Manager of Aviation Technical Services for the Port Authority of New York and New Jersey. He also noted that Mr. Muldoon's bio and Scope of Services had been provided to the Panelists. The Scope of Services makes clear that while Mr. Muldoon works under FAA direction, he will be available for consultation with various interest groups and Panel members.

- Mr. Egan questioned why eight Panel meetings were mentioned in Mr. Muldoon's Scope of Services. The facilitator noted that there are four meetings scheduled, including today's, and two additional meetings to be scheduled on the draft SDEIS. Mr. Scarano explained the need to build in some flexibility in the contract scope.
- Panelists requested contact information for Mr. Muldoon. He said he would provide it through Mr. Scarano.
- Mr. Tye asked if Mr. Muldoon could help the Panel consider whether peak period pricing and other demand management strategies could offset the need for a runway. Mr. Muldoon responded that he could do so.
- Mr. Rushing asked that all Panelists be apprised of all questions posed by Panelists to Mr. Muldoon. Mr. Muldoon suggested that he forward an e-mail of all questions presented to him to Mr. Scarano, who could then forward the list of questions, and answers when available, to all Panelists.

Presentation on Sources of Delay

- Beverly Jones, of S, H & E, presented an overview of the sources of delays at Logan Airport. She reviewed the various delay tracking systems, including FAA's OPSNET, DOT's Air Travel Consumer Report, and FAA's CODAS system. She highlighted that all of the existing delay tracking systems have serious limitations, in that they do not count several types of delays, like those under 15 minutes, or those resulting from mechanical problems or otherwise under the airlines control. As a result of the limitations on the existing data collection, it is necessary to develop simulation models to estimate delay reduction impacts. Ms. Jones reviewed Logan's national ranking on delays. In 1999, Logan was 4th most delayed in the DOT Consumer Report, and 8th most delayed in the OPSNET data. In 1998, Logan ranked 2nd in the DOT Report, and 7th in the OPSNET. Logan ranks 8th in total passengers and 14th in operations nationwide. Based upon simulation of the 1998 flight schedule and the actual hourly weather observations from that year, Ms. Jones presented estimates of the various sources of delay at Logan. Of the total delay, 43% occurred in VFR (clear weather) conditions. Northwest wind conditions occurred in 37% of VFR conditions. However, 70% of clear-weather delays occurred during northwest wind conditions. The new runway would have eliminated 68% of the VFR delays in 1998 and 32% of the total delay.
  - In response to a question from Mr. Rushing about when a delay is considered "significant," Mr. Nicosia-Rusin from FAA noted that a traditional benchmark of significant airport delay is 20,000 hours annually. Logan's annual hours of delay have been 120,000.
  - Ms. Welch asked whether efforts are underway to improve the delay tracking systems to include all the delays that are missing from the current data. She also asked how airline overscheduling and its impact on delays is factored in to the current models.
  - Mr. Tye noted that there is a question where to put the regional aircraft if they are a sizeable contribution to total delay. He asked if other regional airports could handle some of these flights, and achieve the same delay reduction as the runway. Mr. Tye requested data on how much regional airlines contribute to the delay.
  - Mr. Rushing asked about how Logan would rank if hours of delay were reduced. Ms. Meehan, President of S, H &E, noted that it is difficult to calculate this without

modeling activities at all other airports. Mr. Nicosia-Rusin offered that although not accurate enough to publish, a sense of the impact on Logan's ranking could be determined by considering that total simulated delays were reduced by about 32%. You could say then that this might represent a 25% reduction in the flight delays recorded in OPSNET, and make your own judgement on how that would affect the rankings. Mr. Rushing asked if it is possible to find out where the delayed flights are coming from or going to. Ms. Meehan noted that this is possible to produce.

Presentation on Peak Period Pricing

- David Hollander of S, H & E, gave an overview of the Peak Period Pricing (PPP) proposal evaluated in the draft EIS. He described a previous Massport PPP initiative, the PACE program, which was developed and implemented in the late 80's, but overturned in a lawsuit. He described how the $100 to $150 peak period fee proposed in the DEIS was developed, and the anticipated delay reduction results. He showed that current operations at Logan are within the 120 operations per hour capacity, and therefore PPP invoked at 110 operations per hour would not have much delay reduction effect. However, if operations go above 120 per hour, as is predicted for the future, then PPP would have significant delay reduction results. That was the rationale for including a monitoring program and trigger for PPP in the DEIS mitigation plan. He further outlined a proposed exemption program for situations in which PPP would reduce flights to communities that need the current number of flights, specifying that these communities would be allowed two flights in peak periods that would be exempted from the peak period fee.
    - Ms. Welch noted that letting the delays escalate to the trigger point before invoking the PPP did not make sense. She asked whether the PPP could be developed from the beginning, setting a trigger that could start as soon as it was reached, thereby advancing the several months of rulemaking that would be needed to implement the program. Richard Litteri, a Massport attorney, commented that the rulemaking process is a state DOT process, which might take six months to conduct. Ms. Welch suggested that Logan become a national model and implement PPP prior to the construction of a new runway.
    - Mr. Hollander was asked if PPP is in place anywhere in the U.S. He responded that it is not.

Presentation on PPP and Other Demand Management Strategies

- Fred Salvucci, Former MA Secretary of Transportation and Professor at MIT, gave a presentation on PPP and other demand management strategies. He began with a statement that he was not representing the views of any other groups in his remarks, but was speaking from his own viewpoint. In his presentation, he proposed that the airport needs to find a way to increase load factors, make other airports and transportation modes more attractive, and conduct sensitivity analysis of various capacity levels at the airport to determine a reasonable level of operations. He noted the need to work with LaGuardia Airport to prevent gridlock on the Boston/New York routes. He further noted that many prior mitigation projects for Logan activities have not been implemented, creating credibility problems for new mitigation proposals. He

suggested that the existing injunction could be used to create enforceable commitments to address RW 14-32 impacts.

- Mr. Salvucci outlined several demand management options, in addition to PPP:
  - Terminal/gate regulation (set number of movements per hour)
  - Asking airlines to consolidate flights voluntarily ("jawboning")
  - Flat landing fees with off-peak discounts
  - Expanded use of Logan Express buses to TF Green, Worcester, Manchester, South Station, and Rte. 128 rail station
  - Expanded high speed rail to Worcester and Springfield via an inland route
  - Upgrade Logan's rail connection, including South Station
  - Pilot test a change in the FAA's first-come/first-serve policy for certain, small aircraft types
- Lt. Governor Swift and Mr. Litteri discussed how demand management strategies could be designed to avoid the legal problems that the PACE program faced, and there was general agreement that a PPP program could be designed to avoid those problems.
- Ms. Welch advocated that a regional intermodal solution and PPP be implemented prior to any runway construction. She further noted that the affected communities do not agree with Mr. Salvucci when he suggests the possibility that a new runway be constructed with restrictions of use only in NW wind conditions.
- Mr. Butler pointed out problems with some of Mr. Salvucci's suggestions, including
  - the impossibility of changing the first come/first serve policy,
  - the move to eliminate, not create, slots at most airports,
  - the lack of connection between ground access and RW14-32,
  - the fact that demand management could be viewed as interfering with interstate commerce, especially if the number of flights that would trigger PPP was artificially lowered,
  - take-offs are not a problem at Logan, and
  - the United Airline changes in San Francisco were not induced by demand management approaches, but by United's pilot strike.

- When the Panel was asked for views about the improvements in the SDEIS on the issues of PPP, Ms. Welch responded that she would like to see PPP included in the Preferred Alternative from the beginning. Others suggested that any PPP program be designed to withstand legal challenges.

III. Public Comment

- Marty Pepper Aisenberg, from Save Our Heritage, asked whether it was within the jurisdiction of the panel to implement demand management or in their jurisdiction to recommend to FAA certain demand management strategies. Mr. Scarano responded that is was more likely the latter.
- Dan Wolf, President of Cape Air, talked about the impact of PPP on airlines like his, with small aircraft, but who do not contribute to the delays nor compete with larger aircraft for runway space, since they use the 2500 foot RW33R-15L. He also said the regional jet fleets are being purchased by airlines for over $10 million per plane, and that a $150

PPP fee might not make much of a difference to those airlines. He thought other forms of demand management might be more effective.

- Bob D'Amico from the City of Boston, questioned a statistic used in the discussion, asking whether it included arrivals and departures, or just arrivals. It was clarified that in bad weather, arrivals are reduced to 45 per hour, not all operations.
- Blossom Hoag from CARE and the Sierra Club asked for clarification about whether flights leaving the gate on time, but delayed awaiting take off, were considered on-time flight departures. Panelist John Butler responded that the flight could be considered delayed if it took off late.
- An aide to Representative Robert DeLeo noted that the Representative had been present for a portion of the Panel meeting, but regretted not being present to make public comment due to a conflicting appointment. He may submit comments to the Panel in writing.

IV. Planning for Next Meeting

The Panel reviewed and revised the draft meeting agenda for September 6. The Panel agreed to meet beyond 7:00 PM if necessary for that meeting, but, given Ms. Welch's inability to stay beyond 7 PM, adjusted the schedule of presentations to fit most of the Panel deliberations in the 4:00 to 7:00 time slot.

V. The meeting adjourned at 4:00 PM.

Boston Logan International Airport

Supplemental Draft EIS (SDEIS) Panel

Minutes

July 26, 2000

I. Agenda (See attached)

- The Panel convened at 4:07 PM

II. Attendees (See attached list)

- Mr. Rushing was not present; the House of Representatives was in session.

III. Discussion

Presentation on Multi-Modal Transportation Planning by Kevin Sullivan, MA Secretary of Transportation

- Secretary Kevin Sullivan provided the Panel with extensive information about efforts underway by Massachusetts, and neighboring states, to improve the coordination of all modes of transportation. He described the following initiatives:
  - Road signage for all regional airports, including signs in RI and NH
  - Expenditure of $154 million in highway funds "flexed" to transit and train projects
  - Dialogue with RI that resulted in eight rail trips per day from MA to Providence which will also serve Warwick/TFGreen Airport when the station is completed
  - The commitment of $385 million for the widening of Route 3 from 128 to the NH border
  - Investigation of a partnership with NH to encourage rail service between Nashua and Lowell
  - Massport efforts to increase flights at Worcester Airport from 9 to 19 per day
  - Manchester Airport evaluation of the environmental impacts of a new access road
  - Development of an intermodal facility in Wilmington, MA
  - Rehabilitation of Worcester's Union Station
  - Development of a business facility at Hanscom
  - Promotion of the Accela train for a lower fare than the NY shuttle from Logan
  - South station connector to Logan via the new Silver Line
  - Expansion of MA commuter rail, which is now the 4th largest in the country and the fastest growing
  - Development of bus service in the Urban Ring
  - MBTA Blue Line expansion
  - Initial planning for the North Station/South Station rail link
  - Development of smaller airports by MA Aeronautics Commission

- Mr. Egan asked if there were other efforts involving more than one state in aviation planning. Mr. Scarano responded that this is a first effort of this scale, to his knowledge.

- Ms. Welch asked the Secretary about plans for improving the Blue Line, which have been put off several years. The Director of the MBTA responded that they are pursuing the capital program for this and the rail service from South Station to airport through the Ted Williams Tunnel.
- Mr. Tye asked about what numbers of passengers could be diverted from Logan. Mr. Sullivan responded that growth is at regional airports, not at Logan. Lt. Governor Swift noted that it is not easy to determine if regional airport growth is totally a diversion of Logan traffic. Ms. Meehan (S, H. & E) added that roughly 1/3 of new passengers are new travelers brought into the market by low fares, and another 1/3 are diverted from Logan.
- Mr. Scarano asked about the development of a rail line from Lawrence to Manchester, and Secretary Sullivan responded that the priority is on the line between Lowell and Nashua, where there are existing rights of way.
- Ms. Welch asked if bus service could be instituted from Woburn to Manchester, in addition to the Woburn-Logan service. The Secretary noted that he is trying to encourage this service.
- Ms. Welch asked how close to completion the North Station-South Station rail link is. Mr. Sullivan remarked that it is a $3-$6 billion project, and will not happen without considerable time and effort to identify and secure the funding.
- In response to a question about the Urban Ring, Mr. Sullivan clarified that a transit rail system was much more difficult to achieve than a bus service along the ring. The bus service is in the planning stage. The price for the transit service is several billion dollars, and this project is competing with the North Station-South Station rail connector for funding.

<u>Summary Comments on Regionalization and Forecasting</u>

- Ms. Orenstein asked the Panel to comment on how the SDEIS should reflect their concerns about forecasting and regionalization. Mr. Scarano asked the Panelists to consider whether the forecasting covers a reasonable range of scenarios. In response, the Panelists made the following comments.
    - Ms. Welch asked if a different kind of forecast, one with a lower low passenger estimate and a lower high passenger estimate, could be developed and used to understand how much diversion to regional airports should occur. She also asked if this revised forecast could be used to evaluate airline overscheduling and aircraft mix.
    - Mr. Tye asked how to avoid a new runway for a problem (NW winds) that occurs only 20% of the time. He asked if traffic could be prioritized and/or diverted, as happens in bad weather.
    - Ms. Welch noted that, while there are many pieces in place or in planning for multi-modal transportation, there is no integrated, coordinated planning process, and what does exist does not offer a vehicle for citizen input. Lt. Governor Swift noted that the New England Council of Governors has sponsored a New England Transportation Initiative, which is the vehicle for interstate planning and cooperation on multi-modal issues.
    - Lt. Governor Swift noted that a strength of both the regionalization analysis and the forecasting done for the EIS is that there is careful tracking of regional

airport users. This helps create understanding of what is driving regional airport use. She recommended that this tracking continue.

Panel Administrative Discussions

- The minutes of the previous meeting on July 13 were finalized and accepted.
- Ms. Orenstein noted that in an effort to increase public access to the panel operations, agendas and presentation slides (when in the compatible electronic format) will be posted on the FAA web site.
- The Panel briefly discussed its upcoming visits to four regional airports on August 16 and 28. Panelists had previously asked for passenger forecasts and market projection information for these airports, and Mr. Scarano noted that this information would be requested from the airport directors for presentation during the site visits. Lt. Governor Swift also noted that it would be helpful for the Panelists to receive information about the decision making structure and lines of authority between the states and the airports.
- Mr. Scarano announced that the FAA had decided to hire an independent consultant for the Panel. He anticipated the consultant would be on board in mid-August. Mr. Egan asked whether this would delay the Panel process and the FAA decision on the SDEIS. Mr. Scarano said FAA remains committed to its goal of a final SDEIS by April, 2001, but that reaching the goal is dependent on Panel events and analysis that are difficult to predict.
- The Panel set dates for interim meetings after the August and September meetings, in case they will be needed. The new dates are September 6 and October 12, from 4:00 to 7:00 PM. The list of meeting dates will be revised and posted on the website.

Overview of Logan Airfield Operations, Joe Davies, FAA Tower Manager

- In preparation for understanding delays at Logan, and the potential impacts of the proposed project on those delays, Joe Davies presented an overview of how Logan airport operates. He explained the air traffic control system in general, and airspace around Logan, and the location of the runways, taxiways, and terminal areas. He then described the configurations of runways that the controllers use, their efficiency, noise and environmental restrictions, and operational needs in VFR and IFR. He concluded by saying that the taxiway, minimums, and runway 14/32 would improve the options available for air traffic control, and also would provide a greater ability to use the Preferential Runway Advisory System (PRAS).
- Ms. Welch asked how well the airport was complying with the PRAS system. Mr. Davies noted that recent data showed that some goals were met, while others were not. Mr. Egan asked if RW 14-32 would allow airport to better meet PRAS goals. Mr. Davies response was yes.
- Mr. Tye asked whether small planes could be diverted to other airports during NW wind delay periods. Mr. Davies responded that it would be illegal. Federal law requires aircraft to be accommodated on a first come-first serve basis.

Observer Comment

- Susan Black, Marketing Director for the Worcester Airport, commended Massport for their efforts at developing the Worcester Airport, and noted that Worcester looks forward to the Panel's visit to the Worcester Airport.
- Peter Koff of AIR said he had sent a letter to Jane Garvey commenting that the Panel process has not spent enough time on issues which would need to be addressed in the SDEIS. He distributed copies of his letter to the panelists.
- Blossom Hoag of the Sierra Club and CARE commented that Mr. Sullivan's presentation did not have many numbers to back it up. She also commented about how undesirable it is to have the North Station-South Station connector pitted against development of the Urban Ring.
- Steve Lathrop, from Hull, commented on the inadequacy of passenger volume and operations analysis. He suggested the Panel ask what might cause more passengers on fewer aircraft. He suspects that operations forecasts are too high, but noted that forecasts are often optimistic and need to be tempered with realtime or very recent data. He also remarked that the Panel has spent too much time on what environmental improvements can be expected from a new runway, and not enough time at looking at alternatives to reduce delay. He asked the Panel to take a broader perspective.

Panel Discussion of Public Outreach Issues

- Ms. Welch asked the FAA to hold community meetings, scheduled in the evenings to encourage attendance, about the Panel process. These meetings could be attended by Panelists if they desired, and might be sponsored by the Citizen Advisory Council (CAC) for the Airport. She proposed that a meeting with the CAC happen in September, and that three additional meeting happen in October to increase the outreach to several geographic regions.
- Mr. Butler and Mr. Egan objected to these outreach meetings, noting that a large number of community meetings have already been held on the runway issue. Mr. Butler noted that these meetings would not meet the Panel's objective of providing input to FAA.
- Mr. Tye suggested that the public's questions should be put in writing. He also suggested that a Panel meeting could be held in the evening to accommodate more public observers.
- Mr. Scarano noted that Mr. Rushing and Lt. Governor Swift (who had already left this meeting) needed to be consulted on this issue. Ms. Orenstein suggested the Panel return to this question at the next meeting.

IV. The meeting adjourned at 7:15 PM.

Boston Logan International Airport

Supplemental Draft EIS (SDEIS) Panel

Minutes

July 13, 2000

I. Agenda (See attached)

- The Panel convened at 2:35 PM

II. Attendees (See attached list)

III. Discussion

Organizational Issues

- Mr. Scarano opened the meeting with a statement that it was his hope that the Panel would devote most of the meeting to substantive discussion of regional transportation issues. He noted the presence of Todd Burger, an expert on rail service forecasting, and mentioned the plan to have the MA Secretary of Transportation attend the next meeting to discuss regional multi-modal transportation planning. Facilitator Suzanne Orenstein reviewed the agenda, noting that in an effort to make up time after delays at the last meeting, the focus for this meeting would be on Panel discussions, and public comment would be taken only if time allowed. Ms. Welch asked that time be allotted for Panel discussion after each presentation, not solely after the first two presentations and at the end of the meeting. The Panel agreed to address questions during the presentations, in an effort to encourage Panel discussion.
- The minutes for the June 22 meeting were reviewed. No corrections were made. The June 22 minutes were finalized and will be placed on the web site.

Forecasting Presentation (continued from past two meetings)

- Ralph Nicosia-Rusin, FAA Airport Capacity Program Manager, began this portion of his forecasting presentation with a review of his previous presentations regarding projections for numbers of passengers and numbers of flight operations at Logan. He continued the presentation with explanations of how the forecasts for passengers and operations used for the DEIS were consistent with those developed for other studies. He reviewed criticisms of the forecasts, addressing issues regarding confidence levels (he noted that by using a range of forecasts, confidence levels could be close to 100%), and whether the data used for the forecast was current. Ms. Welch asked whether the forecasts could be further updated to use 1999 and/or 2000 data, in addition to the update from 1993 to 1998 in the Brown Book. She noted this would have the advantage of incorporating equipment upgrades and producing more accurate noise information. Mr. Nicosia-Rusin responded that the data will always be behind the present because of the 6-8 months it takes to produce the model results. He further noted that comparisons of one year to another were not as significant as comparisons of the build and no-build alternatives. He ended by stating that when delay reduction benefits of the proposed Airside Improvement Project are evaluated using both the low and high ends of the forecast ranges, the results do not differ significantly, except for the

increase in effect of Peak Period Pricing at the higher passenger estimates. This leads him to conclude that the forecasts are sufficient for the evaluation of the project.

- Discussion following Mr. Nicosia-Rusin's presentation included the following additional comments and questions.
  - Are there demand management techniques in use at other airports, other than Peak Period Pricing, that should be considered for Logan, and that could be evaluated using the forecast and other models?
  - Ms. Welch noted that an FAA web site presented data comparing delays at various airports that showed that delays at Logan were decreasing by 6%. Mr. Butler responded that delays at Logan are not down, and that airports are not directly comparable, because some have parallel runways that provide more flexibility for reducing delays. Logan's runways are intersecting, so managing delays at Logan is more complicated than at other airports. Mr. Nicosia-Rusin noted that delays at Logan are affected by incidence of weather conditions that are not consistent from year to year, so decreases might occur, but might not be consistent over time. After considerable discussion of the delay issues, the Panel asked for a break down of all causes of delay by source and frequency. Noting that some sources will be unknown, S, H, and E agreed to provide a breakdown of causes of delay for the discussions at the next meeting on airfield operations.
  - Mr. Tye commented that he was not comfortable with conclusions that the benefits of the runway were borne out by the forecasting process. He heard a lot about the benefits of a new runway but nothing was presented regarding the need for it. He views the Panel's role as examining the need for the Airside Improvements Project, and finds the conclusions premature.

Presentation on Regional Alternatives

- Deb Meehan, President of S, H, & E, gave an overview presentation of how regional alternatives to Logan were factored into the Logan passenger and operations forecasts. She noted that the forecasted passenger numbers include an estimate of 7 million passengers diverted to regional airports, rail service, and video conferencing and how the estimates for those diversions were developed. She noted that regional carriers will continue to need to serve Logan because 59% of their passengers are connecting to non-stop flights that are not available from T.F. Green or Manchester, and that the remaining regional carrier passengers have Boston as their destination. In the discussion of regional alternatives, the following comments and questions arose.
  - Mr. Tye commented that he was interested in options for using regional airports to the maximum extent available as a way to reduce operations at Logan. Mr. Scarano and others responded that both Manchester and Providence were growing at unbelievable rates, but that their growth would be constrained by the physical and land availability, even after major improvements in access and facilities.
  - Ms. Welch asked if airport plans and projections for all regional airports could be researched and reported to the Panel. Ms. Meehan and FAA agreed to provide this information. Ms. Meehan also explained how some regional airports compete with others, which also might limit growth. For example, Bradley, Manchester, and Providence all serve part of the area that Worcester airport could serve.

- Mr. Tye and Ms. Welch asked about whether Logan should de-emphasize the market for short-haul trips. They asked for information about the average aircraft size for short, medium and long haul trips, and how these factors affect Logan operations. Ms. Meehan agreed to provide this information.
- Several panelists, and Mr. Burger, commented on the factors needed to promote growth at regional airports, including proximity to the traveling population, ease of access to the airport, and sufficient service to meet travelers needs for flexibility.
- Ms. Welch requested that the FAA research how many airlines will use a 5000 foot runway and whether they will make a specific commitment to do so. Mr. Scarano noted that this would be addressed at the next meeting.
- Mr. Egan remarked that much has been accomplished in the regional airport development process and that it appears that all of the Panel Members support improvements in the regional transportation arena. When he asked whether the opponents of the Logan Airside Improvement Project also opposed the expanded use of Hanscom Field, Ms. Welch responded that the Mayor's representatives support increased use of Hanscom Field.

Presentation on Potential Impacts of Rail Service on Logan Forecasts

- After a short break for an executive session, Todd Burger, an independent transportation consultant formerly with Arthur D. Little, and project manager for the Strategic Assessment Review (SAR) in 1993, presented his view of the realities of diverting Logan passengers to high speed rail. He noted some factors that may reduce the desirability of the high speed rail alternative in the Northeast Corridor, including potential rail traffic delays. He noted that rail service between Boston and TFGreen airport might be more successful than anticipated, but that this might adversely impact passenger use of Worcester airport. Lt. Governor Swift noted that MBTA, not Amtrak, would be operating the TFGreen rail service. Mr. Burger noted that he thought the forecast estimates for Logan, which are quite consistent with the forecasts used in the SAR, are on-target in spite of slight changes in the rail diversion numbers. He also noted his conclusion that rail service will not be a substitute for runway 14/32.

IV. Observer Comment

Because State Representative McManus, from Worcester, asked to address the Panel, having traveled to the meeting from his vacation to do so, time was made available for some public comment. Representative McManus spoke appreciatively about Massport's efforts to increase air traffic at Worcester and noted Worcester's strong support for additional air service from Worcester airport. He stated that Worcester's central location and strong industry should create a market for additional service. He noted that he and others in Worcester are convinced that the access road to the airport can happen, especially if the market demand is there to support it. He noted that he did not see any conflict between Runway 14-32 and growth at Worcester, and that he thought both should occur.

The meeting adjournment time of 6:00 PM was reached before public comment from Steve Lathrop, from Hull, and Mark Cestari from Shuttle America could be heard. They were asked to make their comments at the next meeting on July 26.

V. Next Meeting

The next meeting is on July 26, from 4:00 to 7:00 PM at the Volpe Center, 55 Broadway, Cambridge, MA. The agenda will include the following items.

- Synthesis discussion among the Panel about the status of the forecasting and regional issue discussions
- A presentation on efforts to integrate multi-modal regional transportation by the MA Secretary of Transportation
- Initial discussion of the Logan airfield operations and delay factors
- Discussion of whether and how Public Outreach about the Panel process should occur.

The Panel agreed to extend the time of its August 22 meeting, which will now be 11:15 AM to 4:00 PM, in order to allow more time for discussion of airport capacity and peak period pricing. The Panel also agreed to follow through on visits to the regional airports, tentatively scheduled for August 16.

VI. The meeting adjourned at 6:03 PM.

Information Requests from July 13 Logan SEIS Panel Meeting

Item	When To Provide	Who Will Develop
1. Examples of demand management techniques, other than Peak Period Pricing, used at other airports	In background materials for August 22 meeting on PPP	FAA
2. Details of all sources of delay at Logan, what proportion of delays are caused by what source, how frequently they occur, and what the trends have been historically.	At July 26 meeting, send out before meeting, if possible.	S,H, &E
3. Information on passenger growth projections and plans from regional airports, including Portland, Pease, Manchester, & Bradley	Prior to July 26 meeting	FAA
4. Information on what is being done to increase use and access for regional airports	Prior to July 26 meeting	S, H & E
5. Specific data on average aircraft size by length of haul, & how average size affects Logan	Prior to July 26 meeting	S, H, & E
6. Information on how many regional airlines will use and acknowledge commitment to use 5000 foot runway.	At July 26 meeting, or prior to August 22 mtg. on airfield capacity	??
7. Potential for improvements at Manchester Airport to affect long-haul/short-haul mix.	Prior to July 26 meeting	S, H, & E
Outstanding requests from previous meeting		
A. Geographic illustration of sensitivity of noise forecasts	Prior to July 26 meeting	FAA – Ralph Nicosia-Rusin
B. Geographic presentation of impacts of forecasts on runway utilization	Prior to July 26 meeting	FAA – Ralph Nicosia-Rusin

Boston Logan International Airport
Supplemental Draft EIS (SDEIS) Panel

Minutes for Meeting No. 2A
June 22, 2000

I. Agenda (See attached)

- The Panel convened at 4:00 PM

II. Attendees (See attached list)

III. Discussion

Organizational Tasks

- In the review of the **agenda**, the facilitator stated that the goal for the meeting was to complete the presentations on forecasting and begin the discussion of regionalization as it relates to forecasting, if time allows. Mr. Rushing noted that he did not receive background information on regionalization and that it was his view that there should be no discussion of this topic at this meeting. Mr. Butler responded that background information was available in the Brown Book. Mr. Scarano noted that FAA agreed that it would direct panelists to relevant sections of the brown book. He proposed that we return to the question of whether to discuss regionalization when the forecasting discussion was completed, at which time it would be known if there was time available to begin that discussion.
- The **minutes** for the previous meeting were revised to correct a quote from Mr. Rushing, and to clarify a response from Mr. Scarano. The minutes were accepted as revised and are ready for posting on the web site.
- Mr. Scarano clarified that the **meeting date for the next meeting** was incorrectly stated in the FAA memo for this meeting. It is July 13, not July 26. Ms. Welch questioned the usefulness of conducting the Panel meeting on regionalization in Manchester. Community groups who attend the meetings as observors would not be able to be present if the meeting was not in the Boston area, and regionalization is a very important issue for these groups. The Panel agreed that visits to regional airports are important, but that the meeting on regionalization could be conducted in the Boston area. The location for the July 13 meeting was changed to Cambridge, and the start time will remain 2:30 PM.
- **New Procedural Guidelines provisions** governing dissemination of information to panelists and contacts with the press and external decision makers were considered and finalized. In reviewing the guideline concerning notice to other panelists before contacts were made with external decision makers, the panelists acknowledged that this guideline would not affect contacts with the decision makers who appointed them, namely, the mayor and the governor. It

would also not affect discussions with the FAA Administrator and others that arose coincidentally at meetings and in other non-Panel forums. The Panel added a specific guideline concerning contacts with the press, namely, that panelists would avoid characterizing the views of other panelists in press contacts.

- Ms. Welch raised the issue of the need for an independent **technical consultant** to assist the Panel members. Panelists discussed this issue for some time, with some panelists expressing the view that the consultants who developed the DEIS should be adequate, and others arguing for independent consultants. Two panelists expressed the view that the Panel should not go any further in its work program until a technical consultant was hired. The Panel identified several possible roles for the consultant, as follows.
  - Help answer "what if" questions from panelists;
  - Identify alternatives to views in the Brown Book
  - Provide independent evaluation of elements of the Preferred Alternative

  Options for obtaining technical consultation for the Panel also were identified:
  - Use S, H, & E
  - Use FAA experts
  - Look for an independent consultant
  - Do homework on own
  - All of the above

  Concerns about hiring a technical consultant included that it might slow down the process, where the funding would come from, and what would be the result of conflicts among the consultant views.

  Mr. Scarano noted that the federal procurement guidelines might be prohibitively time intensive, and that it was his preference that a consultant to the Panel be hired through MassPort. Mr. Tye noted he did not care where the funding came from, as long as the consultant worked for everyone on the Panel. <u>The Panel decided to await FAA's decision about whether and how to provide technical consultation</u>, given that the issue had already been presented to Jane Garvey.

<u>Forecasting Presentation</u> (continued from previous meeting)

- Ralph Nicosia-Rusin, FAA Airport Capacity Program Manager, continued his presentation about the forecasts of passenger levels and operations projected for Logan Airport for the future. In addition to highlighting issues around fleet mix and historical passenger and market trends, Mr. Nicosia-Rusin showed how the forecasts and changes in the forecast would affect noise and delays. There were several questions and answers discussed during the presentation.
  - Ms. Welch asked whether anything could be done to put more people on larger aircraft, thereby decreasing the number of flight operations. Mr. Nicosia-Rusin showed how the low and high fleet scenarios built into the forecast took these possibilities into account.

- Ms. Welch asked about the sensitivity of forecasts to errors. Again, the response was that by using a high and low scenario, any changes are within the extremes that have been studied.
- Ms. Welch asked for additional information about the noise impacts, noting it was easier to see the impacts on a map than on a graph. Mr. Nicosia-Rusin agreed to develop a geographic illustration for the next meeting. Ms. Welch also asked that slides show land areas for changes in runway utilization, and Mr. Nicosia-Rusin agreed to provide that information also.
- The presentation was stopped prior to the discussion of possible impacts from regional airports on the forecasts, for lack of time. Mr. Scarano noted the inadequacy of the time available for discussion and recommended that time be made available at the next meeting for additional questions on forecasting.

Observor Comments

- Gerry Falbo, of Winthrop, noted that he preferred to have community people respond to the issue of independent consultants, not those satisfied with the MassPort consultants.
- Steve Lathrop, from Hull, presented some research that showed airports with rapidly increasing emplanements also had increases in efficiency. He also expressed the view that the technical consultant needed to be either adversarial, with one for each view of the expansion, or a single consultant for the Panel as a whole.
- Anastasia Lyman, of the CAC, noted that the noise contours in the SDEIS are predicated on optimal use of PRAS. However, there is no assurance of optimal use, and the CAC is not in support of PRAS as currently used.
- Blossom Hoag, of the Sierra Club and CARE, noted that Massport's mailing to frequent flyers asking for their support of the runway was not constructive. She also asked if observors could have handouts used during the Panel meetings.

IV. **Next Meeting**

- The Panel identified the following topics for the next meeting.
  - Continue the forecasting presentation and discussion, including impacts of regionalization, geographic presentations of noise and runway utilization, and criticisms of forecasting components of the DEIS document.
  - Discuss regionalization, including an overview of the components, expectations for growth at regional airports, and impacts from increased use of rail due to high speed routes.
  - Whether and how the Panel should conduct meetings in locations proximate to affected communities.

V. The meeting adjourned at 6:40 PM.

Boston Logan International Airport
Supplemental Draft EIS (SDEIS) Panel

Minutes for Meeting No. 2
June 7, 2000

I. Agenda (See attached)

- The Panel convened at 3:00 PM

II. Attendees (See attached list)

III. Discussion

Organizational Tasks

- Mr. Scarano updated the Panel concerning FAA follow-up to the previous meeting. He noted that a web site has been established and the "Brown Book" will be available on it; that the Brown Book was distributed to ARC members, and letters went to local legislators describing the availability of the report. The summary of the significant public comments on the DEIS, with responses, was also distributed to Panel members.
- Ms. Orenstein reviewed the agenda, noting the proposed public comment period. The Panel agreed with the proposal.
- The Panel reviewed the summary of the April 26 meeting, and suggested the date be added in the heading. The minutes were accepted and FAA agreed to post them on the web site.
- Scheduling for future meetings was completed. The dates agreed upon are:
  - June 22, as a supplement to the June 7 meeting
  - July 13, 2:30 to 5:30 PM, at Manchester Airport
  - July 26, 4:00 to 7:00 PM
  - August 22, 12:30 to 3:30 PM
  - September 27, 4:00 to 7:00 PM
- The Panel reviewed the Procedural Guidelines, including Public Involvement Options. Mr. Rushing requested addition of several items previously discussed, including the agreement that materials would be provided to the panel at least 7 days before meetings and earlier if possible, and that all Panelists will receive any information requested by any panelist at the same time as the requesting panelist.
  - Mr. Egan asked if the schedule outlined in the guidelines, for completion of the Panel process by April 1, 2001, called for a Record of Decision (ROD) by that date. Mr. Scarano responded that the Final EIS will be available on that date subject to the progress of the scheduled meetings, and the ROD would be issued some time after that but could not specify any specific time because considerable internal FAA coordination would be required.

- In response to questions from the governors representatives to the mayoral representatives about a meeting held with the mayor and Jane Garvey, Mr. Egan proposed that all Panelists agree to forego advocacy with political leaders, press, and the courts regardless of the outcome of the Panel process. His suggestion was not adopted. Mr. Rushing suggested that a groundrule be adopted specifying that if any panelists desired to meet with political decision makers or the press, they would notify the rest of the panelists first. The Panel did not object to this suggestion, and Ms. Orenstein agreed to draft this provision for Panel review.
- Ms. Orenstein suggested, and the Panel agreed, to consider the Procedural Guidelines a working document that is open to revision as the Panel sees fit. <u>The Panel agreed that the Procedural Guidelines were accepted and should be posted on the web site.</u>

<u>Presentation on the Interim SDEIS – "The Brown Book"</u>

- John Silva, Manager of Environmental Programs for FAA New England, began the substantive presentations with an overview of the requirements for an EIS, and a description of the components of an EIS.
  - In response to a question from Mr. Tye regarding what action would not require an EIS, Mr. Silva noted that construction of a runway at a small airport where there were no environmental impacts might be an example of a federal action with no significant impact.
- Deborah Meehan, President of S, H &E, air transportation consultants, gave a detailed presentation describing the Draft EIS and the Interim Supplemental Draft EIS. She explained that the ISDEIS, or Brown Book, represents the effort to incorporate public comments that began prior to the inauguration of the panel. Ms. Meehan described the differences between the two documents, and noted that the Preface in the Brown Book was a good overview of the comparison and revisions in the Brown Book.
  - Comments and questions on Ms. Meehan's presentation included:
    - Page 18 of the presentation, which outlines the geographic distribution of Logan passengers, is not in the Brown Book. Ms. Meehan noted that it would be added.
    - Service between Worcester Airport and Atlanta was not included in the description of the service provided there. It will be added.
    - Lt. Governor Swift noted that there are many acronyms used throughout the Brown Book, and that they should be explained. The presenters noted that the Generic Environmental Impact Review for Logan includes a glossary. Panelists can request a copy of the GEIR from FAA or Massport.
    - Mr. Tye asked if there is an opportunity to move some of the small aircraft operations to another airport, and what could be done to reduce

the number of small aircraft carrying few passengers. He also requested data on all of the sources of delay, not just NW winds. These topics will be addressed in depth at the July and August meetings.

- Ms. Welch noted that it was frustrating to have so much information presented without having the ability to question assumptions and give an alternative view. Mr. Scarano responded that as each component of the SDEIS is taken up in depth in future meetings, her questions and comments will be addressed in detail.

Presentation on Forecasting Methodology and Results

- Ralph Nicosia-Rusin, FAA Airport Capacity Program Manager, began a presentation on forecasting of passenger use and resulting operations projections for Logan Airport. His presentation was only partially completed, and will be continued at the June 22 meeting.
  - Comments and questions raised by Mr. Nicosia-Rusin's presentation included:
    - Mr. Butler asked about noise associated with the forecast, as related to Stage 2 and 3 fleet components.
    - Ms. Welch asked how increased regionalization would affect the forecasts. In response, the range of variation between forecasts, from 29 million passengers to 45 million passengers was described in more detail, to show that the current forecast range covers most likely scenarios.
    - Mr. Butler asked how consolidation of the airlines, such as the proposed merger between United and US Airways, was factored into the forecasting.
    - These questions were briefly considered as time allowed, and will be discussed in more detail on June 22.

IV. Observer Comments

- Steve Lathrop from the Hull Airport Committee, noted that overwater take-offs also go over Hull, sometimes at an altitude of 1500 feet. He also suggested that the preferred alternative be compared to current conditions, and that noise data in the DEIS is erroneous. He requested that the slide presentations be included on the web site.
- Ed Pignotti from the Boston Chamber of Commerce commented on the critical nature of the airport to the region's economy. He noted the need to solve the delay problems, and expressed support for significant improvements of regional airports.
- Blossom Hoag representing the Sierra Club and CARE noted the need for high speed rail improvement projects to include the link between North and South Stations, and noted that Chelsea is not the only area impacted adversely because the Harbor Islands also are subject to environmental and noise impacts.

- Bruce Thatcher asked when information will be on line on the web site, and was given the response that most is available now. He suggested that future Panel meeting dates be posted on the web site. He further noted that pilot non-compliance with Land and Hold Short Operations might increase delays. As a Roxbury resident, he is interested in Roxbury's receiving some focus regarding Logan impacts although Roxbury may not be impacted directly.
- Bernice Maider from the CAC spoke about the cumulative impacts that communities are feeling from the Big Dig, bridge construction, the convention center development, and development in South Boston. If air travel demand increases as predicted, there will be a need for more jets, which will fill the time available from delay reduction activities. She asked if there will be a guarantee on unidirectionality, and distributed clippings showing press coverage of Logan delays seldom, if ever, mentions the NW wind problem.
- Rick Rodes from CARE and a resident of Winthrop noted his community's concern about the centerfield taxiway, and its health effects. He further asked if other airfield projects would be considered in the Panel discussion, and it was clarified that the Panel will address all components of the alternatives discussed in the DEIS, not just runway 14/32.

V. Action Items

Task	Whom
Post final minutes for all meetings to date on web site	FAA
Post Procedural Guidelines on web site	FAA
Draft additions to procedural guidelines	Facilitator
Post meeting dates on web site	FAA

VI. Plans for Future Meetings

- The Panel agreed to meet on June 22 from 4:00 PM to 6:30 PM to continue the discussion of forecasting and begin the discussion of regionalization. Lt. Governor Swift noted that she would not be available for that meeting and encouraged the Panel to meet without her present.
- The meeting scheduled for July 13 will be held at the Manchester Airport, and will continue the discussion of regionalization. The Panel reviewed the regionalization issues outlined by FAA in the workprogram, and the issues raised by the mayoral appointees, and agreed that the meeting should include a focus on those items. The meeting will also include a tour of the Manchester airport and a briefing about its operations. This is all subject to coordination and approval of the Airport Authority.
- **VII. The meeting adjourned at 6:20 PM.**

Boston Logan International Airport
Supplemental Draft EIS (SDEIS) Process

Minutes for Panel Meeting No. 1A
April 26, 2000

I. Agenda (See attached)

- The meeting convened at 4:00 PM

II. Attendees

- John Butler was absent but he had previously noted he would not be able to attend. We had committed to date and in effort to avoid any further delay the meeting would be conducted in his absence. Because of his previous experience with the project this absence would not be significant to his understanding of this evenings activities.
- Mr. Joe Davies, ATCT Manager for Boston Logan was in the audience and introduced by the Chair.

III. Discussion

Agenda Item 1 - Review and Acceptance of the Minutes for March 28th.

1. Introduction of the Facilitator

- Mr. Scarano introduced Ms. Suzanne Orenstein who had been retained to facilitate the Panel proceedings.
- Ms. Orenstein provided a brief resume of her previous experience.
- She noted that she had attended the first Panel meeting.
- She stated that she will strive to speak to Panel members between meetings to ensure that all their concerns are being properly understood and communicated.
- She went over her role saying she would ensure that everyone is heard and the meeting is run efficiently.
- All members had been previously provided a copy of her resume and the scope of her services on this project.
- Ms. Welch asked for the difference between the Chair and Facilitator. Ms Orenstein responded that the Facilitator:
  - Ensures that the conversation is balanced and remains focused.
  - Works for the entire panel, including one-on-one meetings.
  - Is not a mediator in the process.
  - Keep ensures that the meeting stays on schedule and runs efficiently.

  Basically the Chair introduces the topic and the facilitator facilitates the discussion. The Chair would also be the position to make decisions on certain issues and Panel suggestions that arise during the discussions.
- Mr. Scarano stated any reasonable suggestions to assist the facilitation would be reviewed and added to the scope.

2. Review of Minutes

- Mr. Tye questioned who prepared the Work Program and the schedule. He noted it appeared "capped". Mr. Scarano clarified that the Work Program was prepared in response to Lt. Governor Swift's request for a schedule at the March 28th meeting.

The program summarized the activities ahead in a narrative format. The Panel prior to each meeting will develop each issue in more detail.

- Mr. Tye also asked for a copy for the DEIS "Response to Comments. The FAA acknowledged they would provide this information at the next meeting **(noted as an IOU Item).**
- At Lt. Governor Swift's suggestion the minutes will be amended to reflect that a FEIS will be ready in approximately 12 months.
- Ms. Welch added that should be a schedule we hope to attain but it is not a commitment.
- Mr. Egan brought the frequency of meetings and the need to move through the topics quicker than proposed in the Work Program. Mr. Scarano responded that the monthly frequency was necessary to prepare for each meeting.
- The Chair anticipates the Final EIS to be published in 12 months.
- Panel concurred to tentative schedule based upon reasonable accommodating any significant issues that arise and with the understanding that if a topic runs over the scheduled time a supplementary meeting will be scheduled rather than allowing unfinished business to push the work program out in time.
- The Lt. Governor asked what the Minutes would be used for – are they part of the official record? Mr. Scarano responded by saying that the Minutes would be used to capture the important points and decisions for FAA to use to prepare the best possible EIS.
- Lt. Governor then for a clarification on a statement about the Interim SDEIS at the end of the Minutes (Page 4): re: FAA was active part of in of the Report review?
- Mr. Tye wanted to know if FAA was endorsing the conclusions of the interim SDEIS report.
- Mr. Scarano said **no** but acknowledged that the FAA probably said at the March 28th meeting that the effort went well beyond what was typically required in an EIS. He also acknowledged that the statement at the end of the March 28th Minutes was an added after the meeting after he deliberated on the subject.
- There was agreement that the idea of adding notes after the meeting should be treated differently.
- Mr. Egan requested that the minutes be amended to reflect the fact that: The FAA stated that the report went well beyond that which is required that the FAA read the report and had no arguments with it. The FAA acknowledged to amend the minutes to reflect the position noted at the March 28th meeting **(noted as an IOU Item).**
- Mr. Egan requested that the Facilitator review the Minutes prior to distribution to the Panel.

Agenda Item II - Public Process and Overview of the Issues

1. **Public Process**
   - Mr. Scarano introduced the topic and indicated the items noted on the agenda forwarded to the Panel were suggestions and by no means a requirement. He was open to all Panel suggestions.
   - Ms. Welch stated the Panel needs to hear suggestions on topics and share information with the public.

- Lt. Governor Swift said that the final product needs to have credibility – open and considerate of all views.
- Mr. Egan said the document needs to reflect traveling public in general.
- Mr. Tye said public input is what it's all about.
- Ms. Welch noted that public meetings need to be accessible by public transportation.

Discussion of public meetings topic by topic versus after several topics ensued.

- Lt. Governor Swift said that public input at the end of the process would be helpful and that people have strong views that may be changed.
- Mr. Egan felt that public meetings would not be helpful unless there were new things because the issues have already had a public forum.
- Mr. Tye said he would invite public input and that he needs much more information. He asked that Ms. Orenstein decide how public involvement should be carried out. She noted the request **(It is listed it as IOU item).**
- Rep. Cushing said that credibility was important and since not everyone has had the opportunity to provide input on issues that the Panel may frame, e.g., regionalization.
- Lt. Governor Swift talked about a web site for public input. Rep. Rushing seconded the idea and said he also favored face to face meetings.
- Mr. Tye and Ms. Welch agreed on asking the facilitator to work on the public process.
- Lt. Governor Swift and Mr. Nicosia-Rusin spoke about the need to use public meetings to inform and educate, with the idea that FAA has to decide on the issues.
- Ms. Orenstein summarized the thoughts on this subject of public process.
  - There was no unanimity on the need for public involvement.
  - Use the facilitator to work on a public process plan.
  - Public already well exposed.
- Ms. Welch said that more public involvement is needed because Interim SDEIS is very different from previous Draft EIS.
- Rep. Rushing said Interim SDEIS could be distributed to libraries, ARC and on the Net.
- Ms. Welch said that politicians needed it.
- Mr. Scarano expressed a concern that FAA would begin receiving comments from those who would obtain a copy of the report and would have to respond to those comments. This issue could be covered in a cover letter that could accompany the document.
- There was agreement to offer the Interim SDEIS (Brown Report) to communities.

Topic shifted to overview of the issues (view graph of prospectus issues was shown on screen).

- Ms. Welch introduced a list of additional potential issues (The Panel was given a copy.) was developed in conjunction with Mr. Tye and Rep. Rushing that should be addressed in the SDEIS. (See note below on same subject.)
- Re: Item I – Induced Demand , Capacity. Lt. Governor Swift said some items on the list might be covered by FAA's list. Need to work items into Work Program.

- Discussion of issues within existing agreements, e.g., Can additional traffic be handled in accordance with the parking freeze?
- Rep. Rushing would like to discuss "off line" EJ and DOT policy reference their E.J issue.

Agenda Item III - Agenda for Panel Meeting No. 2

1. **Discussion of schedule.**
   - Agreement that schedule is tentative for production of FEIS in 12 months.
   - The dates were agreed to for meetings through Meeting No. 4. They were:
     - May 31, 2000 at Volpe TSC 4:00PM - 6:30PM
     - June 22, 2000 at Volpe TSC 4:00PM - 7:00PM
     - July 26, 2000 at Volpe TSC 4:00PM - 7:00PM

     Dates for Meeting No. 5 and 6 would be revisited.
   - Mr. Scarano said FAA would integrate the primary issues presented in Ms. Welch's supplemental paper into the Work Program where FAA thought they could best fit. In preparing the issue for the next meeting we would discuss the plausibility of actually assessing the individual topics as part of the Work Program.
   - There was agreement to move aviation forecasting from meeting No. 3 into the next meeting, Meeting No.2 - Overview of the EIS.
   - Ms. Welch requested that the presentation include the differences between the DEIS and the SDEIS.
   - Mr.Nicosia-Rusin suggested that the next meeting include a description of how forecasts affect environmental impacts. He also suggested presentation of forecasted demand around a "sensitivity analysis" to determine how significant changes are as a result of those forecasts.
   - Ms. Welch spoke to the desirability of having their consultant present at the net meeting.
   - Mr. Tye expressed the need to have the most credible information.
   - Mr. Egan objected to listening to the CAC's consultant.
   - The CAC consultant may be making a presentation on forecasting at the next meeting.
   - Ms Orenstein summarized the IOU's for the next meeting.

Boston Logan International Airport
Supplemental DEIS Process

Revised AGENDA
Meeting No. 1[1]

March 28, 2000
5:15 PM - 8:00 PM

Massachusetts Transportation Building
Conference Room No. 1 on the 2nd Floor

1. **Introductions**

2. **Opening Statement**

3. **Logistics for Future Meetings**
   Frequency, Day and Time, Length of Meetings, Location, Guidelines, Facilitation

4. **Roles and Responsibilities of FAA, Panel, Massport, Public**

5. **FAA Overview of Existing Planning and DEIS Process.**

   NOTE: The following items were not discussed and deferred until the next meeting in approximately 2 weeks.

6. **General Review of the FAA Prospectus (Deferred to Meeting 1A)**
   - **Public Process: Providing Input and Disseminating Information**
   - **Issues: See Prospectus - Section V**

7. **Agenda for Next Panel Meeting. (Deferred to Meeting 1A)**

****

[1] Revised Agenda effective March 28, 2000

Boston Logan International Airport
Supplemental Draft EIS (SDEIS) Process

Minutes for Panel Meeting No. 1

I. Agenda (See attached)

- The meeting convened at 5:15 PM

II. Attendees (See attached)

III. Discussion

Introductions:

- Mr. Scarano introduced himself and acknowledged several others in the audience (Derosier and Leo, Massport, Higgins, EPA, D'Amico, City of Boston Transportation, Dusseault, Borgioli, ATCT, Flieger and Harris, FAA Air Traffic.
- The Panel introductions were Lt. Gov. Jane Swift, Ray Tye, State Rep. Byron Rushing, Mary Ellen Welch, John Butler, and Dick Egan, Panel Members, as well as Ralph Nicosia-Rusin and John Silva, FAA Airports and Panel Technical Support staff

Opening Statement

- Mr. Scarano read his opening statement (See attached).
- Rep. Rushing noted that Mr. Scarano's reference to Ms. Garvey's citation omitted a phrase. (The attached statement has been annotated to include the phrase inadvertently omitted.)

Logistics for Future Meetings

- Mr. Egan suggested the meetings be held every 2 weeks to expedite.
- Lt. Gov. Swift also asked whether it would be possible to hold frequent meetings to expedite the process and what FAA anticipated as a time frame to complete the process.
- Mr. Scarano highlighted:
  - It was expected that it would take 10 – 12 months and it would be difficult to schedule meetings with an interval less than 1 per month.
  - Preparation for meetings, especially when new material was required was a factor.
  - He also highlighted that it would take at least 10 meetings.
  - The time frame also included specified time required (a) to comply with the NEPA process and (b) respond to comments provided during the public review process. The DEIS process took 2 months to respond to public comments.
- Mr. Egan asked that the process and that all meetings be recorded.
- It was accepted that minutes would be recorded and FAA would consider tape recordings for subsequent proceedings.
- Mr. Scarano noted that FAA was going to provide a Facilitator and would be available for the next meeting. Rep. Rushing noted that no future meeting should be scheduled until the Facilitator is on board. We all concurred with this point.
- Ensuing discussion about the Facilitator's role followed. It was agreed that FAA would provide the Panel with a position description.

- Acknowledging his limited awareness of many of the issues associated with this Boston Logan issue Mr. Tye asked that all information be provided in sufficient time to prepare for subsequent meetings.
- Mr. Scarano offered to meet with him or any Panel member separately and brief them on the subject. It was agreed that FAA would provide an agenda and any associated material in sufficient time to prepare for all meetings.
- Mr. Egan asked whether the Panel should establish a policy about speaking with the media.
- Mr. Scarano suggested that the Panel should consider this, but he was not adverse to media being present at meetings because it was a form of a public process.
- The panel reached a consensus that as a Panel, they would only issue statements with unanimous consent.
- Mr. Egan inquired as to the format of the meetings and the possibility of the Panel meeting in private to facilitate more expression of ideas.
- Mr. Tye commented that the dialogue held throughout this process would speak for itself.
- Rep. Rushing observed that this discussion reflected a concern about "trust" in the process and this was why a Facilitator was required.
- Mr. Scarano replied that he was uncertain about the legal requirements for a public meeting, but felt that the process would benefit more by keeping it open.

Roles and Responsibilities

- Mr. Scarano requested that the Panel discuss their views of their "roles" and responsibilities. Rep. Rushing concurred that it would be good but requested that Panel have an opportunity to return to this topic after a facilitator has been brought on board.
- Lt. Gov. Swift felt that her role had already been well defined by Ms. Garvey's letter to the Governor. Rep. Rushing concurred with the Lt. Gov.
- Mr. Egan spoke about regulations covering the adequacy of the document and whether the Panel's role should determine such, and perhaps regulations should determine the Panel's review and not the quality of the document. He also wished to know what other SDEIS had been completed elsewhere in the U.S., as well as when and how.
- Mr. Scarano replied that for the most part there were no specific regulations as to how this process should be conducted but that other airports had conducted supplemental studies and that each was unique to their specific needs. The FAA accepted his request as an IOU.
- Ms. Welch suggested that public meetings could be held at certain delegated points in the future, each using a community involvement consultant. Meetings should be held to cover more limited topics as the FAA develops the SDEIS. She stressed the point that there was a definite need to coordinate all information with the public.
- Mr. Scarano noted that these were items on "Public Input and Dissemination" and suggested the discussion be deferred until that topic was raised. **Note**: Because the Panel meeting was concluded before that agenda item was reached the topic was deferred to the next meeting. Ms. Welch's point warrants a full discussion at that time.
- All Panel members agreed to address the need for public involvement at the next meeting.

- The other item on the agenda not discussed this evening was the framing of the issues highlighted in the Prospectus attached to Ms. Garvey's letter to the Mayor and Governor. Moreover, Mr. Scarano asked whether the Panel concurred that those issues are generally the general concerns expressed by the public during the DEIS process.
- Mr. Scarano cited as an example of framing an issue for the next meeting the discussion of the new runway would have to include examining the adequacy of its length in light of the introduction of regional jet technology and growth.
- In response to questions as to whether these issues have already been resolved Mr. Silva added that information from the consultants would be given to the Panel. We view this as a starting point but anticipate the need to clarify and in some cases expand the analysis.
- Ms. Welch reiterated that independent consultant rather than one consultant might be more beneficial to the panel and FAA should consider her request. This topic was discussed at some length with others noting that the Panel had to be the best source of values and judgement.
- Ms. Welch also asked for a commitment that experts would be available to the Panel.
- Mr. Scarano responded that his opening statement contained a commitment that if the Panel felt additional analytical work was necessary the FAA would consider it. He also noted that FAA would rely on Massport to provide the resources to conduct additional work.
- Lt. Gov. Swift made the point about Massport credibility. She made the recommendation that the Panel not require resources to be spent on providing additional information if the Panel would not commit to accepting the credibility of the source of the data prior to reviewing the results.

FAA Overview of Existing Planning and DEIS Process

- This was a slide presentation by Mr. Scarano generally highlighting:
  - The planning since 1991 leading up to the decision by Massport to pursue the environmental process for a new runway.
  - How that environmental process (NEPA and MEPA) proceeded to date.
  - Where we are at the start of this SDEIS and what will occur from this point to conclude with an EIS and Record of Decision (ROD).
  - It also noted the Panel's role in that process and where it concluded.
  - The panel will help guide our response to the comments received during the formal public process on the SDEIS and before we prepare the Final EIS.
  - The point that this was strictly a Federal process.
- The Panel requested and received a copy of the slide presentation.
- There was also a specific request for a copy of the "New England Service Study" that was referred to in the Planning slide presentation. FAA accepted this as an IOU.

General Review of the FAA Prospectus – Public Process and Issues
Agenda for Next Panel Meeting

- To conclude the meeting at the 8:00 PM scheduled time all agreed to reconvene in about 2 weeks to complete discussion of both these items. The Panel agreed to send schedules to FAA for identification of a mutually convenient time and date.

- Lt. Gov. Swift asked that the FAA develop and furnish the Panel with a Work Plan for all subsequent meetings. FAA accepted this as an IOU.
- To conclude the meeting FAA provided each member with the Interim SDEIS, reminding each member to refer to the FAA opening statement regarding the FAA position on this document.
- In deliberating the issue of the report after the meeting the FAA is incorporating an additional statement for the record.

  The FAA was an active participant in reviewing the report and was instrumental in commenting and suggesting changes to its content. Notwithstanding that fact, the Panel should not assume from its content that the FAA has adopted, either in part, or as a whole document the final conclusions. In preparing the Final EIS the document will be subject to changes based on the SDEIS deliberations with the Panel and the responses received during the final public comment process.

IV. IOU's

- The following is the status of the IOU's developed at this meeting.

#	Item	By	Remarks
	IOU's Meeting #1		
1.	Copy of FAA Statement	FAA	Copy Attached
2.	Copy of Minutes for Meeting No.1.	FAA	See Above Notes
3.	Provide draft Work Plan for Mtgs.	FAA	Work in Progress
4.	Copy of NE Air Service Study	FAA	Copy Attached
5.	Copy of Slide Presentation on Planning Studies and NEPA process.	FAA	Provided at Meeting
6.	Other Examples where a "supplemental process" utilized • Where, When, How?	FAA	Work in Progress
7.	Copy of PD for Facilitator.	FAA	Work in Progress
8.	Copy of original SDEIS.	FAA	Work in Progress
9.	Provide Scheduling Information to FAA	Panel	Information Pending
10.	Schedule Meeting No. 1A to Complete Agenda	FAA	Work in Progress

The meeting concluded at 8:00 PM.

****

Minutes prepared by FAA April 3, 2000[1]

[1] The minutes will be reviewed, discussed and accepted as part of the Agenda for Meeting 1A.

Subject: Boston International Airport Supplemental DEIS Process - Meeting No.1 March 28, 2000.
Opening Statement by Vincent Scarano, FAA, Airports Division, New England Region

1. COMMITMENT

When the administrator asked me to serve as the Chair for this Panel it was a matter of great personal and professional pride. I am asking you to trust me and to seek out the answers to your questions during this process from my office. In serving in her behalf I am committed to:

- Guiding the panel and ensuring that we stay focused on our purpose.
- Making this an objective process.
- Understanding all viewpoints.
- Making no decisions about the environmental process until we have completed the process.

2. PURPOSE

The Panel is asked to confront this controversial R/W project by engaging in a fair and open process with the hope of:

- Helping FAA understand all viewpoints.
- Sharing your insights.
- Discussing, evaluating, understanding and perhaps even reconciling divergent views.
- Suggesting alternative approaches.
- Providing information to the public.
- And finally counseling and guiding the decision-makers to find the right solution.

In some respects this process is more then influencing a decision on whether or not to build Runway 14-32.

- Either choice will influence decision-makers on transportation policies for Boston, the region and even the national airport system.
- Equally important is the fact that either way you create environmental choices that impacts the communities and region positively and negatively.
- Finally, decisions about Logan Airport also impact the economic development of Boston and the region.

Therefore in progressing through this process you need to think broadly about the airport issues and impacts and not just about building or not building a runway.

3. THE PROCESS

This process is about the panel working with FAA.

- The starting point for our discussion is the interim report that will be provided to the members tonight. Whether you agree or disagree with its content, it is a data source from which to develop an understanding of the information to date.[1] Please do not get hung up on what it is called.

The existence of this report does not mean that:

- The process will be limited to the existing information.
- Limited to analyses and evaluations that have been completed.
- Issues or options that warrant additional assessment or review will certainly be a consideration.
- FAA will call upon the panel's viewpoint before making a decision about performing new work.
- If there is evidence that another consultant should conduct the analytical work FAA will also take that under consideration.

This is a FAA environmental process and we are following the National Environmental Policy Act process and therefore:

- Ultimately we will prepare a supplemental DEIS that will be made available for public comment.
- The process will conclude with FAA issuing a final EIS and ROD.

4. TRUST

The lack of it has continually plagued the relationship between the community and aviation interests. Therefore, in my role as Chair I am adding one more commitment and that is:

- To ensure that trust and credibility will not become an issue jeopardizing the validity of this process.
- There may be differences of views but it will be based on honest opinions on how a fact is viewed.
- Creating an open process will be one the first subjects of tonight's meeting.
- How we provide information to the public will be a first step in creating a positive attitude on trust.

5. IN CLOSING:

For this process to be objective it is also critical that there be a balance in our thinking. It is best expressed by referring to Jane Garvey's personal statement to the Governor and Mayor on February 10th.

> "For this process to succeed, those who believe that r/w 14-32 can play a positive role in improving Logan must be prepared to help **identify the other parts of a reasonable solution**[2], to consider mitigation that can eliminate any negative impact and be prepared to consider that there may be alternate solutions that do not include a runway. Those who have opposed the runway need to clearly identify concerns and be prepared to consider that there may be an acceptable package of actions that includes the runway."

The challenge therefore is for all of us to move the process forward in the spirit of commitment and compromise.

---

[1] Refer to the Minutes Mtg No.1 (page 4) - an additional comment concerning the FAA position on the Report is noted.
[2] The section in bold print was inadvertently omitted during the reading of the statement to the Panel on March 28th

SDEIS Panel Questions

Questions Submitted by Mary Ellen Welch, Logan SDEIS Panel Member

#	Comment	Response
1.	May this panel have the T.F. Green forecasts? In fact, may we have the marketing forecast and analysis from the Manchester, Worcester, Green, Pease, Portland, and Bradley airports and have a FAA presentation to compare with the Logan forecasting of market issues?	Appendix B of this Supplemental DEIS/FEIR presents all available planning forecasts and a summary of predicted environmental impacts for the regional airports that surround Logan – T.F. Green, Manchester, Hanscom and Worcester. Chapter 2 of this Supplemental DEIS/ FEIR describes Massport's marketing forecast for the Worcester Airport.
2.	Could we have an explanation of the differences between the M.P.A. delay model and the FAA delay model? The delay numbers are different. Why?	Appendix C of this Supplemental DEIS/FEIR describes measures used by the FAA and US DOT to assess delays at airports, the limitations of those measures, and the use of simulation models for estimating delays. Chapter 1 of this Supplemental DEIS/FEIR compares delay simulation estimates produced by the FAA's delay model to estimates produced by the DELAYSIM model used for the Airside Project analysis. Chapter 4 of this Supplemental DEIS/FEIR contains a discussion of the models used by the Airside analysis to estimate delays. The Logan Airside modeling includes only those delays produced by conditions at Logan, and it tallies all delays experienced by Logan traffic.
3.	What will be the projected number of all flight operations off of all runways in 2010? Could we have them listed by runway in a scenario with 14/32 in place?	This Supplemental DEIS/FEIR provides forecasts for a range of future, long-term activity levels. The projected number of flight operations by runway end and project alternative are presented in Appendix E. While the Draft EIS/EIR attributed these forecasts to 2010, the impact of the regionalization suggests that Logan will not reach these levels until 2015. A new 2015 scenario which contains a higher number of regional jets is fully analyzed in the Supplemental DEIS/FEIR
4.	Alternative 2 (no 14/32) is left out of the SDEIS as a feasible and prudent alternative. Why?	The Airside Project Draft EIS/EIR presented detailed results for all project alternatives for all forecast fleets. This Supplemental DEIS/FEIR contains detailed results for a range of fleets comparing the Preferred Alternative to the No Action Alternative. The comparison is limited in this Supplemental DEIS/FEIR in order to focus attention on the relevant analysis. In this Supplemental DEIS/FEIR the results of all Alternatives, including Alternative 2, are summarized in the Appendices: Appendix C contains operational results, Appendix E contains noise results, and Appendix F contains Air Quality results.

#	Comment	Response
5.	Reinstate alternative 2 for a comparison study so the public can understand, and the impacts of 14/32. Without the comparison there is no demonstration of those populations that would receive increased impacts if 14/32 is built.	See response to Question 4. The new analysis of the high regional jet fleet in the Supplemental DEIS includes Alternatives 1 and 2, as well as the No Action and Preferred Alternatives.
6.	PRAS is used in ISDEIS to plan for a shared noise model. PRAS has not been used by the tower most of the time.	Chapter 4 of the Supplemental DEIS/FEIR provides an evaluation of PRAS performance using existing measures for monitoring PRAS and demonstrates that the FAA has improved its performance relative to the PRAS goals. The analysis also shows that Runway 14/32 will substantially enhance the FAA Tower's ability to increase PRAS performance with respect to both annual and short-term goals. The Preferred Alternative (Alternative 1A) mitigation program includes additional reporting requirements recommended to enhance the monitoring efforts.
7.	Contours should be re-done reflecting the use of PRAS to reflect reality. PRAS needs to be re-worked with an approved minimizing overall noise before sharing noise in a system model. May we have information, analysis demonstration, and presentation of this?	The goals of the Airside Project are to reduce delay, increase the airport's efficiency and improve airfield safety in an environmentally responsible manner. In addition to reducing delays and improving efficiency, Runway 14/32 would also give the FAA air traffic controllers considerably more flexibility, which would allow them to improve achievement of PRAS goals and redirect many flights over water and away from close-in communities. The addition of Runway 14/32 would be the single most important mechanism for achieving a more equitable geographic distribution of aircraft operations. While more people are added to the more distant contours (60 and 65 DNL), the close-in populations achieve substantial relief (70 and 75 DNL). Without the proposed runway, demand at Logan will increase the airport's reliance on Runways 4 and 22, disproportionately impacting communities north and south of the airport.
8.	In 98 – 99, operations are down. Delays are down by 6%. Other airports, Detroit & Denver, both with 5 runways, have increased delays. 118% → Detroit Both have 500,000 plus operations, 43% → Denver	Depending on wind, weather and demand, delays at Logan will vary from year to year. Regardless of the annual variation in the number of delayed flights reported by the FAA, Logan remains one of the most delayed airports in the country. Logan is more severely delayed than either Detroit or Denver. For the year cited, 1999, Logan was the 7th most delayed airport, while Detroit ranked 10th and Denver was 29th. Further, Logan experiences significantly more delays per aircraft operation than Detroit or Denver. In 1999, there were 30 delayed flights at Logan for every 1000 operations, compared to 21 for Detroit and only 3 for Denver. Analysis in Chapter 4 demonstrates that if Runway 14/32 were available in 1998, Logan delays would have declined by 32 percent.

#	Comment	Response
9.	Logan is decreasing in delays on its own. Why?	Refer to Question 8.
10.	In the discussion on fleet mix, it was stated that 45% of the fleet are 9-18 seat turbo prop airplanes. This 45% of the fleet serves 10% of the total passengers. Where is the analysis of a plan to minimize the 45% mix? Generic EIR, '98; Passengers increased 3.8%; Aircraft increased 5.2%	The most recent growth trends at Logan show declines in operations with increases in passenger traffic. In 2000, total operations fell by 3.2% while passengers grew by 1.3%. The average seat size of regional/commuter turboprops (with 9-50 seats) has steadily increased. Moreover, the number of non-jets has begun to sharply decline; in 1999, the non-jets comprised only 39% of Logan operations. In the Supplemental DEIS/ FEIR, a new "High Regional Jet" fleet is analyzed for 2015. In this fleet, turboprops account for only 11% of the fleet while regional jets account for 32%.
11.	May we see demand management techniques from other airports as an approach to curb this unbalanced growth? And could it be done before a new runway is decided on to test it?	Section 3.5.2 of the Supplemental DEIS includes a summary of demand management techniques that have been proposed or implemented at Logan and other airports. Due to the increased congestion that developed at New York's LaGuardia Airport after the AIR-21 legislation last year, the FAA is developing a new demand management policy that will be implemented at LGA in September 2001, and which will provide guidance for other US airports such as Logan. It is important to recognize that demand management (e.g. Peak Period Pricing) and proposed Runway 14/32 address very different delay problems at Logan. Unidirectional 14/32 is designed to reduce delays due to Northwest Winds. It does not represent an increase in Logan's total capacity; rather, it helps Logan maintain capacity when the winds are from the Northwest. On the other hand, Peak Period Pricing is a demand management technique that addresses the problem of airline overscheduling. Massport is committed to implementing a monitoring program, and, if demand conditions warrant, a Peak Period Pricing Program. Other demand management techniques, such as slots or operational caps, are not within the purview of Massport and therefore do not represent realistic alternatives.
12.	'98 comparison for a base seems unfair; 87% of the fleet was Stage 3. Reduction would be 3db if it had been fully compliant. Would this be or make a difference in comparing '98 contours to a future with all stage 3s? Could you program the INM to produce a contour using '98 fleet without stage 2s? This would seem to be fairer for future contour projections for E.J.	Throughout the Airside documents, the relevant comparison for environmental and delay results is Action to No Action within the same fleet. Comparisons across years can be informative, but are not useful for deciding which project alternatives are appropriate for achieving delay reduction benefits, nor what their relative environmental impacts are.

#	Comment	Response
13.	How will the new terminal developments affect airspace capacity, new gates, increase of traffic impacts? Will they affect fleet mix and operations?	These modest changes are expected to increase operating efficiency and level of service somewhat, but to have no impact on passenger levels, ground traffic, fleet mix or number of operations. The terminal developments envision a few additional gates, but a reduction in aircraft parking positions.
14.	How will ground access improvements affect future passenger levels, e.g. Big Dig, South Boston Waterfront.	Major ground access improvements from Boston to an alternative airport or to a major air market, such as New York, are the types of ground access improvements that could impact Logan passenger levels. The Airside analysis takes into account improved access to Providence Airport via rail and high-speed rail access to New York (Amtrak's Acela service). Both of these ground access improvements have a dampening effect on the projected growth in Logan demand. Other ground access improvements have an impact on mode choice to and from the airport, but not impact the decision to use Logan.
15.	Pg. 4-1, 4th bullet. Why did 1999 29M low fleet mix change regarding % of jet operations that would utilize 14/32?	With the improvements of the Preferred Alternative, 52,000 additional jet operations occur over water compared to the No Action Alternative.
16.	The DEIS stated: "75,000 operations (52,000 jet ops.)." The ISDEIS states that out of the 75,000 ops there will be "32,000 jet operations" using 14/32. What changed and why?	See response to Question 15.
17.	Alternative 2 seems to offer an additional 45,000 hours of delay reduction compared to Alternative 1A in the DEIS, Table 4, pg. 6-3, High Fleet Scenario. Why? How does the forecasting address this? There is a need for additional analysis and presentation.	In high fleets, both Peak Period Pricing and the runway result in significant reductions in delay. In low fleets, Peak Period Pricing has almost no effect on delays because airline over-scheduling is not a primary cause of delay in these scenarios. Massport is committed to Peak Period Pricing, along with the runway and taxiway improvements, if Logan begins to suffer from over-scheduling.
18.	When you do forecasting what % of the delays are due to: longer aircraft separation; schedule demand / over-scheduling; air traffic control procedures; noise abatement rules; other restrictions, e.g. weather.	The proposed Airside Improvements address those delays that Massport can expect to reduce at Logan. Figure 4.6-3 of the Supplemental DEIS compares the breakdown of delays during VFR and IFR weather conditions. It also demonstrates the effectiveness of the Preferred Alternative in reducing VFR delays. Reduced Minimums also provide a small reduction in IFR delays, but in general there is little that can be done at Logan to reduce these delays. Figure 4.6-1 shows the VFR delays for 1998 by wind direction, and the dramatic benefit that Runway 14/32 would have on northwest wind delays. Similar data for the new 37.5M High Regional Jet Fleet is presented in Figures 4.7-4 and 4.7-5. Delays due to airline over-scheduling can be estimated by comparing Alternatives 2 and 4 in Table 4.5-3 of the Draft EIS/EIR, and in Table 4.7-2 of the Supplemental DEIS/FEIR. Air

#	Comment	Response
		traffic control separations and procedures were developed by the FAA to maintain safe aircraft operations, and cannot be modified by Massport.
19.	How do these compare to NW wind situation?	Refer to response to Question 18.
20.	What % of the "wake turbulence separation" restriction decreased capacity and increased delays?	In August 1996, the FAA changed the aircraft weight categories used to determine wake vortex separations, and increased the separation between B757s and Small (mostly turboprop) aircraft. With Logan's fleet mix at the time, this resulted in a shift of 12% of Logan's operations from the Large category to the Small category. This increased the approach separations of these aircraft by 1 to 1.5 miles behind Large or B757 aircraft. When Logan is able to use three runways, the Small aircraft are normally assigned to a different landing runway than the jets, so the effect was most important during northwest winds and under IFR conditions. Since 1995/96, the number of Small aircraft at Logan has declined as airlines have replaced them with larger and heavier equipment.
21.	(From Feb. 1999, Draft EIS/EIR, pg. 4-33) (45,000 less hours of delay with Alt. 2)	Refer to response to Question 17.
22.	Could we have a graphic showing the kinds of delays compared to each other, e.g., NW winds vs. other weather delays vs. over-scheduling vs. other airport delays causing Logan delays?	Refer to response to Question 18.
23.	Analysis of all existing and potential delay-reducing FAA air traffic demand management and flight procedures.	The FAA is always studying new procedures to reduce delays. However, there is no technique or management tool that replaces the need for Runway 14/32. The proposed runway is designed to reduce delays in Northwest wind conditions when Logan drops from a three-runway configuration to a two-runway configuration, and occasionally, in severe winds, to a one-runway configuration. A summary of ongoing FAA measures to reduce delays nationwide is presented in Chapter 1 of this Supplemental DEIS/FEIR.
24.	Comparison analysis of same-size airports with similar wind and weather delay-creating factors.	Chapter 1 of this Supplemental DEIS/FEIR compares reported delays at Logan to delays at other similarly sized airports, including northeast airports subject to similar weather conditions.
25.	Comprehensive analysis on runway length and acknowledged intent to use 5000' runway from all airlines using Logan.	Research by the FAA consultant indicates that the proposed 5,000-foot runway is adequate for all turbo-prop, most general aviation, and most regional jet types forecast to operate at Logan. The report of the FAA consultant is contained in Appendix C of this Supplemental DEIS/FEIR.

#	Comment	Response
26.	When you're doing the forecasting, how much regionalization do you include?	To account for the uncertainty associated with any forecasting effort, the Airside analysis considered a range of future passenger and aircraft operation levels. One of the factors that cause this variation is the success of regionalization. In this Supplemental DEIS/FEIR, Massport extended its forecast of 37 million passengers from 2010 to 2015 to reflect the observed impact of regionalization on Logan's growth trend. Chapter 2 of this Supplemental DEIS/FEIR describes the impacts of regionalization on Logan's future demand levels.
27.	What are your methods for dealing with uncertainties, e.g. In Chapter 4 delays, MPA and FAA admit their forecasts are inflated (pages 4-7 and 4-8) as much as 10% above actual '99 operations and off by 2.5 of passengers forecasted for 2010. These forecasts are the same ones used to compare the alternatives and push 14/32.	To account for the uncertainty associated with forecasts, the Airside analysis considered a range of future passenger levels from 29 million (expected to be reached in 2003) to 37.5 million (expected to be reached in 2015), and 45 million (expected to be reached around 2024). Furthermore, the results of the Airside analysis indicate that the delay reduction benefits of the Preferred Alternative are not dependent upon the forecast passenger levels. On the contrary, if the elements of the Preferred Alternative had been available to Logan users in 1998, annual delays hours would have been reduced by 32 percent (Refer to Chapter 4 of this Supplemental DEIS/FEIR).
28.	Please explain, on pg. 4-8, 1st paragraph: "In terms of the hourly demand profile, the 1998 profile has significantly less peaking than the 29M forecasted fleets. The late afternoon peak period in '98 has fewer operations and is shorter than the peaks in the near term forecasts. The '98 demand is "flatter" and produces fewer delays than the 29M high and low profiles.	The shape of Logan's demand profile (hourly arrivals and departures) has an impact on delays. Higher and longer peak periods of aircraft demand result in more delays. Chapter 4 of this Supplemental DEIS/FEIR provides a detailed description of the changes in Logan's demand profile.
29.	Pg. 4-11: During '99 Logan had moderate 20% growth in passengers despite a 2.5% decline in operations. Pg. 18, 2nd paragraph: "In '99 there was a 1.9% increase in passengers." Why is this? Why the difference?	In 1999, Logan passengers increased by 2% over the 1998 passenger level (Note that the 20% reported in the comment and 1.9% on page 4-18 of the Interim Supplemental DEIS distributed to the Panel are typographic errors). Changes in passenger demand are largely a function of changes in economic conditions. As economic conditions improve, passenger demand increases. Changes in the number of aircraft operations can be caused by competitive factors and carrier fleet decisions, as well as other factors. It is generally true in the air transportation industry that the growth in passenger demand outpaces the growth in operations. This is because growth in passenger demand is accommodated through higher load factors or larger aircraft.

#	Comment	Response
30.	If operation levels are rising minimally and passenger levels are declining, thereby impacting forecasts, why the rush for a new runway?	The FAA consistently rates Logan Airport as one of the most delay-prone airports in the United States. The proposed unidirectional Runway 14/32 is designed to reduce delays caused by Northwest winds. Runway 14/32 has no impact on delays that result from increases or decreases in airline schedules. Despite the reduction in aircraft operations in 1999 and 2000, Logan was the 7th most delayed US airport in both years. Please refer to Chapter 1 of this Supplemental DEIS/FEIR for a discussion of delays caused by Northwest winds.
31.	How do you factor into the air passenger predictions for Logan the fact that it is full? Terminals are full, curbs are full, and it's hard to park or get a cab. How do you determine capacity with passenger forecasting?	The ESPR, which Massport files annually with MEPA, confirms Logan's ability to accommodate increases in passenger demand for the foreseeable future. The ESPR describes on going and proposed improvements at Logan in terms of terminals, parking, ground access, etc. The Airside Project utilized a wide range of activity levels, including current and future levels. The Preferred Alternative provides significant delay reduction benefits at current and all future activity levels. See Chapter 4 of this Supplemental DEIS/FEIR
32.	Logan is 11th in operations, 17th in passengers, 18th in cargo. Is this why the delay--too many small planes?	There are a number of factors that cause delay, including wind, weather, fleet mix and demand. Please refer to Chapter 1 of this Supplemental DEIS/FEIR for a discussion of the specific causes of delay at Logan and the proposed improvements for addressing various sources of delay.
33.	With regional airports, high-speed rail, and videoconferences: "It is possible that Logan would not realize the 37.5M passenger level until some time beyond 2010. In fact, if Logan continues on its current growth path, it is likely to achieve close to 34M passengers in 2010." So, why does MPA continue to use 37.5M and 45M passenger levels as representing "reasonable long-term planning levels for use in evaluating the relative merits of alternative airside improvements at Logan"?	Please refer to Chapter 2 of the Supplemental DEIS/ FEIR for a discussion of the impact of regionalization on demand for Logan. This Chapter describes how the regional airports and high speed rail dampen the rate of growth for Logan, delaying until 2015 and 2024 when Logan is expected to reach 37.5 million and 45 million passengers, respectively. The 37.5M and 45M passenger forecasts still remain valid long-term planning projections for Logan. Furthermore, a projected 2010 passenger level of 34 million is bounded by the Airside Planning forecasts of 29M, 37.5M and 45M. Also, the delay analysis clearly demonstrates that the Preferred Alternative would have provided significant delay reduction benefits in 1998 if Runway 14/32 were in place (see Chapter 4).
34.	Pg. 6-20: The contours on 29M Low Fleet forecasts assume a "low level of commuter operations in the mix." But Logan has 45% of its fleet as commuters. How do you explain this?	The percentage of non-jet aircraft in the 29M Low Fleet, 41.8%, is very similar to current conditions at Logan. In 1999, non-jets accounted for 39% of all Logan aircraft operations.

#	Comment	Response
35.	How do you explain discrepancies they found in forecasts and assumptions discussed on pg. 6-30?	Chapter 6 of this Supplemental DEIS/FEIR explains differences between Logan's actual 1998 activity and fleet mix and the forecast 29M Low scenario. The differences do not imply that the 29M Low scenario is unrepresentative of a future scenario at Logan, nor does it imply that it is not instructive for analyzing proposed improvement projects.
36.	It is necessary to have a full air quality analysis on income and minority communities as a basis for projecting future impacts if 14/32 is built?	Refer to Chapter 6 of this Supplemental DEIS/FEIR for a detailed discussion of the Environmental Justice analysis. Low income and minority populations were defined in accordance with Federal Executive Order 12898, the Final U.S. Department of Transportation Order, and environmental justice guidelines from the Council on Environmental Quality. In addition, the analysis of low-income populations was expanded to include households at 150 percent of the poverty level. Even at this expanded poverty threshold the Preferred Alternative does not result in any high and adverse disproportionate impacts to low-income and minority populations.
37.	How do you justify 14/32 as an over-the-water runway when Figure 6.2, pg. 1-4 shows Runway 14/32 actual flight tracks over southwest Boston and south-shore communities after a short stretch of harbor? Flying over Quincy, Dorchester, Mattapan, Hull, Hingham, and Milton are not all over the water.	All jet aircraft departing from Runway 14 will follow noise abatement departure tracks and will be above 6,000 ft when passing over Hull and other South Shore communities. Aircraft on straight-in arrival tracks to the Runway 32 end fly over water longer before overflying communities than aircraft arriving to any other runway end, except Runway 33.
38.	There needs to be a section about land use and social impacts to the Fan Pier and South Boston waterfront development by increased use of Runway 27 if Runway 14/32 is built. 60-65DNL encompasses that area and the 65-70 DNL contour extends into Southie if 14/32 happens.	The 60-65 DNL contour for the Preferred Alternative for the 29M Low scenario, which produces the largest Airside contours, falls within the 1999 actual 60-65 DNL contour over South Boston. Therefore Runway 14/32 and any increased use of Runway 27 do not cause any additional land use or social impacts beyond those that exist today.
39.	How can it be stated (pg. 6-1) that "No one residing in the area exposed to noise above 65 DNL is projected to experience an increase in levels in excess of 1.5dB due to the preferred alternative"? On the same page it states that for 29M. The forecasts show 380 more people will be included in the new 65 DNL contour with the preferred alternative over the "no action" and in the 37.5M High forecast 508 more people will be in the 65 DNL contour (Figure 6.2-5, pg. 6-20, pg. 6-29.)	The reference to the bullet on page 6-1 of the Interim Supplemental Draft EIS ("Brown Book") that was distributed to the Panel refers to the 29M Low fleet. For the 29M Low fleet, the noise increase experienced by these populations as a result of the Preferred Alternative is less than 1.5 dB. This Supplemental DEIS/FEIR clarifies that this point refers to the 29M Low fleet.

#	Comment	Response
40.	Table 6.2-9 shows increased "newly included" populations impacted by an increase of 1.5 dB inside the 65-70 DNL contour. That equals 3,905. Explain this please.	See response to Question 39.
41.	There is no discussion of new terminal developments and how they will impact airspace capacity. Will there be new gates added? Will there be an increase of traffic? What are the impacts?	The delay and environmental impacts of current and future aircraft operations levels are fully reflected in the Airside Project. The 1999 ESPR discusses all landside projects, including terminals and ground access, and Massport's planning forecasts, which are consistent with the forecasts analyzed in the Airside Project.
42.	Pg. 3-1: What does the FAA plan to do about its agreement with the City of Boston not to reduce the minimums.	The FAA did not enter into an agreement with the City of Boston. The agreement between the FAA and Massport stipulates that any modification of the existing approach minimums requires completion of an EIS, even though the setting of minimums is otherwise categorically excluded from the EIS process. Incorporating the analysis of reducing the minimums honors the FAA's agreement with the Massport.
43.	As Green, Manchester, Portland, and Worcester mature, can't those passengers be better served with direct flights without coming to Logan?	Chapter 2 of this Supplemental DEIS/FEIR discusses in detail the passengers that the regional airports can be expected to "recapture" from Logan.
44.	Isn't San Francisco proposing a ban of aircraft smaller than 30 seats (to reduce airside congestion), working with United to use larger planes, and moving commuters to surrounding regional airports? Can't we do that too?	San Francisco withdrew this proposal. Logan serves as a gateway to the national and international air transportation systems for small, remote New England communities that do not generate enough demand to support direct flights to other destinations. Passengers traveling between these communities and Logan on commuter airlines rely on connecting services at Logan to reach their final destination. The regional airports are not a good substitute for Logan in this regard because they lack the demand to support the breadth of services available at Logan.
45.	What are the factors that lead to a "high" or "low" fleet scenario? How can we get a "very low" scenario?	The number of operations and size of aircraft are what separate the high and low fleets. For a forecast passenger level, a "High" scenario assumes a high proportion of small aircraft in the Logan fleet. By comparison, the "Low" scenario for the same passenger level assumes a smaller proportion of small aircraft and thus fewer operations. Through market forces Logan's current fleet is similar to a "Low" scenario. In fact, in 1999 and 2000, Logan's annual aircraft operations had declined due to reductions in regional carrier turboprop flights. If Logan should move towards a high fleet, the proposed Peak Period Pricing Monitoring System will identify that and the necessary action to deter delays due to the over scheduling of a high fleet.

#	Comment	Response
46.	What is the trade-off between reliability and number of aircraft movements per hour? What proportion of time can Logan handle 120 movements per hour? 100? 80? 60? 45?	Logan's highest capacity is 120 movements per hour. The objective of this Supplemental DEIS/FEIR is to maintain this capacity in all operating directions, thereby improving the reliability of the airport. Artificially constraining airport capacity is not a project goal.
47.	What is the private sector mechanism that regulates over-scheduling? Just what is the level that convinces airlines to increase the size of aircraft and reduce the frequency? How do European airports handle this issue? Other US airports? Why can't FAA and MPA aggressively work with the airlines to reduce over scheduling and increase the number of large planes used at Logan?	A mechanism for managing over-scheduling is Peak Period Pricing. The pricing necessary to convince an airline to increase aircraft size or reduce frequency varies with a number of factors including the mix of business and leisure passengers, the number of passengers, existing aircraft size, and the opportunity cost of doing something else with the aircraft. Some European airports have a form of Peak Period Pricing, while others have some form of hourly or daily caps. Massport is committed to implementing Peak Period Pricing if over-scheduling becomes a contributor to delay and has designed a monitoring system to detect over-scheduling.
48.	What are the possible actions to divert passengers from Logan?	The regionalization of aviation in New England is currently underway. As a result of capital investment, service expansion at regional airports and coordinated efforts between Massport and other Federal, state and local agencies, eight out of ten new passengers in New England have used regional airports since 1996. Refer to Chapter 2 of this Supplemental DEIS/ FEIR for a discussion of a new study effort by the New England Region of the FAA and Massport that will identify new efforts to further regionalization.
49.	What is the maximum number of passengers Logan can handle? Both of the above (47 and 48) must have thorough analysis.	The maximum number of passengers that Logan can handle is an indeterminate number. As a service facility, the key measure is the level of service (e.g. queue length and delays) that is experienced by aircraft, passengers and vehicles flowing through the airport complex. These depend on many factors that are constantly changing, such as weather, types of users, etc. Massport's Airside and Landside improvements are aimed at providing a higher level of service for all users, in an environmentally responsible manner.
50.	There is a need to analyze a reasonable fleet mix, which would get the % of the passengers using 15% or 20% of the airside capacity using small regional jets of 30, 50 or 70 passengers. How do we get a more reasonable fleet mix?	This Supplemental DEIS/FEIR analyzes a new fleet that includes a significant number of 30-70 seat regional jets and a small proportion of turbo-prop aircraft. See Chapters 4 and 6 for a discussion of the delays and environmental impacts associated with this new High RJ Fleet. Also see response to question 47.
51.	There should be an analysis of a low reasonable fleet with only 15% of the operations in small aircraft and regional jets and a high reasonable fleet of 22% in order to show the impact that a different fleet mix might have. Back to a previous question,	Refer to Question 50. The broad range of fleets analyzed in the Airside Project clearly indicates that as operation levels increase, delays also increase. The analysis shows the delay associated with Action and No Action for 14 different aircraft operations levels. These are: 1993 historic operations; 1998 actual operations;

#	Comment	Response
	this hopefully would show how reliable the different levels of movement are, e.g. 120 movements an hour; 110, 100, 90, 80 or 70 per hour. We could see what delay happens at what movement rate.	Alternatives 1A and 4 for 29M Low, 29 High, 37M Low, 37M High, 37M RJ, and 45M High; and Alternatives 1, 2 and 3 for 29M Low, 29M High, 37M Low, 37M High, 37M RJ and 45M High. Note that alternatives with Peak Period Pricing (Alts. 1,2,3) result in a lower number of operations than alternatives without Peak Period Pricing (1A and 4) due to scheduled flight cancellations.
52.	There needs to be a different set of figures to be developed as an alternative to the one the MPA uses to illustrate "High Fleet" and "Low Fleet." Their "High" is unreasonable. Their low is still excessive. There has to be a description of the relationship of schedule and fleet mix to reliability. The MPA definition of over-scheduling is too high. Information about how the runways are used and how it affects delay would be more helpful. The definition of over-scheduling could then be relaxed to real information.	Please refer to responses to Questions 50 and 51. The Massport forecasts represent reasonable near and long-term projections of passenger growth and are consistent with the FAA's Terminal Area Forecasts. The future "High" and "Low" fleet scenarios are based on real information regarding the aircraft orders and options of airlines, and assumptions, based on historic and current conditions, of how many regional airlines will operate at Logan. This approach has produced a broad range of future aircraft operation levels for accommodating the projected levels of Logan passenger demand. The future scenarios assume that the rate of increase in aircraft operations is lower than the rate of passenger growth. This is consistent with recent trends and assumes that passenger load factors increase over time. The long-term fleet scenarios assume operations increase by 0.8% to 1.6% average annual growth over Logan's CY 2000 operations. These forecast growth rates are significantly lower than Logan's historic long-term operations growth, which is 2.4% average annual growth between 1980 and 2000. The threshold used to define overscheduling was 110 operations per hour, which is below Logan's normal operating capacity and is reasonable. For information on how the runways are used and how delays at Logan accrue, refer to Chapter 1 of this Supplemental DEIS/FEIR.
53.	The MPA approach analyzes two alternatives, with and without a new runway, using their definition of "high" and "low" fleets. Both show delay returning and exceeding present delay with or without the runway. We need to have different analysis to show how regionalization would answer this issue in a better way using different descriptions of "high" and "low" as described in a previous question as "reasonable" high or low.	Please refer to responses to Questions 26, 27, 33, 50,51, and 54.

#	Comment	Response
54.	If the goal is to achieve a more reliable regional transportation system, the analysis is not "clear weather" or "low wind" but all delay. If the reasonable high/low alternatives with and without an added runway are analyzed, the effectiveness of a new runway could change. The runway would have fewer numbers of planes and the issue of regional jets not willing to use a 5000' runway (as in Atlanta and Philadelphia) would be a part of the study. This analysis is necessary.	The Airside Project analyzes the runway's benefit at 14 aircraft operation levels, including the level achieved in 1998. Regardless of the demand level, the runway provides significant delay reduction because it fixes an inadequate runway system—the lack of a third runway in northwest wind conditions (See Chapter 1 of this Supplemental DEIS/FEIR). By serving the largest concentration of population in New England, Logan Airport plays a critical role in the region's air transportation network. The purpose of the Airside Improvements Project is to reduce delays at Logan that can be alleviated by improving the efficiency and reliability of the airfield. These include delays due to northwest winds, and, when it is a problem, delays caused by airline overscheduling. Reducing these sources of delay at Logan improves Logan's reliability and improves the region's airport system (See Chapter 2 of this Supplemental DEIS/FEIR). The FAA conducted a review of the utility of a 5,000-ft runway at Logan and concluded that the proposed runway could accommodate all turboprops and most of the regional jet types expected to use Logan Airport (See Appendix C of this Supplemental DEIS/FEIR.)
55.	Analysis should be done to show how a new "reasonable" fleet mix would affect total delay and how presumably it would cause a significant reduction in total noise exposure. When there are delays planes are put off to the extent that more fly at night where the noise is louder.	It is correct that delays often push aircraft into the night when aircraft noise is more annoying to people in surrounding communities. By reducing delays that occur during northwest winds, the proposed runway will keep daytime flights from being delayed into the night during these operating conditions. A new fleet using a higher proportion of regional jets, the 37.5M High RJ fleet, was analyzed in the Supplemental DEIS/ FEIR. See Chapter 4 for the operational impacts of the new High RJ fleet and Chapter 6 for the environmental impacts of the new fleet.
56.	If the number of 19-seat aircraft is reduced (which would be necessary if Logan accommodates more passengers), the effectiveness of both 14/32 and the centerfield taxiway changes. This needs to be analyzed.	A comparison of the delay reduction results for the High and the Low fleets, shows that the proposed runway is effective even with the lower numbers of 19-seat aircraft operations in the Low fleet scenarios. The FAA's review of the length of the 5,000-ft runway concludes that the proposed runway would be able to accommodate regional jets. (See Appendix C of this Supplemental DEIS/FEIR.) Further, the analysis of the new 37.5M High RJ fleet, which reflects the FAA's RJ utilization assumptions, indicates that the runway is effective even if airlines reduce the number of 19-seat aircraft and replace them with larger, 30- to 50-seat regional jets. (See Chapter 4 of this Supplemental DEIS/FEIR.) The Centerfield Taxiway will serve all types of aircraft

#	Comment	Response
		operating at Logan, to reduce taxiing delays and thereby environmental impacts.
57.	Again to the centerfield taxiway–how much delay would exist if Logan had 100 movements per hour? There should be some analysis of the sensitivity of delay to the number of operations, and the relationship of the number of operations to aircraft size.	The Airside Project examined a broad range of impacts associated with 14 different levels of aircraft operations, including two historic levels (1993 and 1998). The objective of the analysis was to determine operational/delay benefits and associated environmental effects for the spectrum of likely future demand conditions at Logan. Demand levels associated with artificial caps on hourly operation levels that are well below the airport's VFR capacity were not examined. The centerfield taxiway provides safety and efficiency benefits at all operation levels. The analysis of taxiway delays in the Draft EIS/EIR shows that the centerfield taxiway and the other taxiway improvements provide 15,000 to 22,000 hours of taxiway delay across the range of future operations forecasts.
58.	The safety risks of the centerfield taxiway need to be considered. The taxiway could be mistaken for a runway and the turns could be potential hazards. These issues need analysis.	Practically all major airports with parallel runways, like Runways 4 and 22 at Logan Airport, also have parallel taxiways. Runway markings, air traffic control procedures, and electronic approach guidance during poor visibility make mistaking a runway for a taxiway highly improbable. The Centerfield Taxiway will satisfy all applicable FAA safety regulations regarding its design, construction, lighting, marking, signage, and use.
59.	The queue issue needs to be evaluated as well. If a change in management pushback happened, only a limited number of aircraft could be in a line at one time. There has been a question about queue before as it applies to existing conditions and how this would relate to a new taxiway.	The Centerfield Taxiway is intended to reduce queues and taxiway delays. It will prevent aircraft queues in the northern sector of the airfield waiting to cross runway 4L/22R, and will reduce delays on Taxiway November by allowing aircraft that require Runway 22L for takeoff to bypass the queue for 22R. It will also provide an alternate taxipath when pushbacks interfere with operations on Taxiways Alpha & Kilo.
58.	Holding peak pricing in abeyance until over-scheduling occurs needs to be reevaluated. This would allow a counter-productive pattern to occur and grow before it is addressed by starting peak pricing. There needs to be an evaluation of the over-scheduling today and how peak price would address it and include exemptions and/or discounts for airlines who need it or just adjust their schedules.	The Airside Project has performed a comprehensive analysis of Peak Period Pricing. The analysis presented in Chapter 4 of this Supplemental DEIS/FEIR addresses the issues raised in this comment. To deter over-scheduling without a pre-emptive Peak Period Pricing Program, Massport has designed a schedule monitoring program which is also described in Chapter 4 of this Supplemental DEIS/FEIR .
59.	In a recent article, two Virginia Tech engineers working under the auspices of the FAA devised a new approach in which air traffic controllers could alleviate time delays in a big way. With the involvement of U. of VA, U. of CA, U. of MD, and MIT, they	Comment noted. There are many excellent and interesting delay related studies and analyses underway. Massport's delay reduction program addresses specific delays at Logan that are caused by the lack of a third available runway in northwest winds. This source of delay at Logan cannot be remedied by a national

#	Comment	Response
	developed aviation related computer models to improve airport capacity and reduce delays. Their paper, "Integration of Simulator Models to Evaluate the National Airspace System", describes the bottleneck in the air traffic control system and how to solve it. They developed 3-computer software models that help controllers sequence arrivals and departures in a better way, which reduce time connected with taxiway operations. Please present this approach and how it would address the delay issues.	program focused on the Airspace System. Therefore discussion of the referenced analysis would not be germane to Logan Airside Program. This specific comment was addressed by the FAA during the August 22, 2000 SDEIS Panel meeting. Please refer to the SDEIS Panel meeting minutes in Appendix A of this Supplemental DEIS/FEIR.
60.	Writing in the N.Y. Times on August 13th, Joe Sharkey used a quote from Dante to describe the air traffic gridlock: "Abandon hope all ye who enter here." There were 44,401 delays in July 2000, about the same as July 1999. But July 1998 had 25,672. And these don't count cancelled flights. The thesis of the article is that airlines enjoy record revenues now with fuller planes and have no incentive to do more than pay lip service to complaints. And Congress, under pressure from industry lobbying, didn't act to resolve the issue. Please discuss ways to address this gridlock and over scheduling by airlines.	Massport's Airside Delay Reduction Program is designed to alleviate delays that are specific to Logan, causing Logan passengers to suffer unnecessarily. It does so by offering a full complement of remedies designed to reduce delays associated with an inefficient taxiway system, artificially high landing minimums, northwest winds and over-scheduling.
61.	An air traffic controller from Foster City, CA, recently wrote that "trying to cram more planes into a specific Airspace won't solve delays, it will make them worse." He says bigger planes, especially the huge new aircraft, will make it even worse. He also blames the industry for basing their scheduling on profit motives. He says building more runways at SFO, OAK and SJC will not manufacture more airspace. Please explain this issue and show how it relates to the issue at Logan.	The Logan Airside improvements are not intended to solve the nation's delay problem. Likewise, national delay reduction measures that improve airspace flow will not have any impact on delays specific to Logan, such as northwest wind delays. Massport is proposing improvements at Logan that will alleviate delays caused by inefficiencies in the airport's runway and taxiway system, and by overscheduling if this becomes a problem. The Airside analysis presented in Chapter 4 of the Draft EIS/EIR and Chapter 4 of this Supplemental DEIS/FEIR demonstrates that the proposed runway will virtually eliminate VFR delays that occur because the airport lacks a third available runway in northwest wind conditions.
62.	Since delay is a "given" at all major airports. How much delay is "acceptable" to the MPA?	There are certain delays that Massport can not solve (i.e., aircraft mechanical problems, snow storms, etc.) or are outside Massport's purview (i.e., delays at other airports, airspace delays, etc.). Massport supports efforts to solve these delays but is forced by circumstances to accept them. The delays that are "unacceptable" to Massport are delays that Massport can do something about, such as delays caused by Northwest Winds, airline over-

#	Comment	Response
		scheduling, an inefficient taxiway system, and artificially high approach minimums. The Airside Delay Reduction Program is designed to alleviate these delays in an environmentally beneficial manner. See Chapter 4 and Appendix C of this Supplemental DEIS/FEIR for the amount of delays at Logan that Massport can eliminate with Airside improvements.
63.	How much delay reduction does 14/32 give in non-NW wind conditions and describe how it would work?	Even without northwest winds, unidirectional 14/32 does provide modest delay reduction benefits. In certain other wind conditions, Runway 14/32 can provide a more efficient configuration than those otherwise available. As shown in Figure 4.6-1 of the Supplemental DEIS/FEIR for 1998, Runway 14/32 would have reduced northwest wind VFR delays by 31,200 hours (87%) from 35,900 hours to 4,700; for the other directions combined, it would have reduced VFR delays by 4,600 hours from 16,200 to 11,600 hours.
64.	Can the FAA produce written confirmation to the panel that all airlines flying regional jets will use 14/32 for arrivals and departures?	The FAA does not control decisions made by individual pilots on whether or not to accept a runway. Every landing is unique, in terms of wind, weather, temperature, aircraft loading, pilot experience, and other factors. A study done by the FAA following the SDEIS Panel process suggests that the majority of regional jets will utilize Runway 14/32. See Appendix C of this Supplemental DEIS/FEIR.
65.	From the impacted communities on the South Shore is this concern: They project that the extended axis of 14/32 would intersect with the axis of 15/33. Please detail any plan to manage this conflict. Where will the traffic be routed? Until this is done, one cannot determine the environmental impacts, other than by conjecture	Runway 14/32 is oriented at an angle of 8.5 degrees toward Runway 15R/33L, so the extended centerlines intersect about 5 nm from the runway thresholds. Aircraft approaches to Runway 32 will be conducted along a path parallel to Runway 33L until the aircraft is about ¾ nm from the threshold, where the pilot would make a slight left turn to line up with the runway centerline. Thus the two final approach courses are parallel and separated by about 4,000 feet.
66.	Please evaluate an alternative VFR approach to 33L. It would involve placing a glide slope beacon on Thompson Island, the arrivals coming in over the harbor mouth then guided by the new beacon, making a right turn into the final approach to 33. This would be a true "over the water" approach.	Such a procedure is theoretically possible, and could be better developed using Long Island, or without any additional navaids for aircraft equipped with RNAV (e.g. GPS) and FMS (Flight Management Systems). However, it would involve a sharp right turn (about 45 degrees) at a low altitude approximately two miles from Runway 33L.This would be a very unsettling and unsafe maneuver for large passenger jets, and would be disapproved by the FAA and refused by airline pilots. Commercial turbojets require a stabilized straight approach during the final 5 miles for normal operations.
67.	Please provide and explain all the runway combinations that would be used if 14/32 is put in place. Along with this please show a traffic management plan showing what pilots and controllers will do for approaches,	The runway combinations using Runway 14/32 are presented in Appendix H of the Draft EIS/EIR. The flight tracks for arrivals to and departures from Runway 14/32 are shown in Chapter 5 of the Supplemental DEIS. Most Runway 32 approaches would be conducted in

#	Comment	Response
	missed approaches and departures out to at least 15 DME for each runway combination.	VFR conditions, but simultaneous dependent approaches to 32 and 33L are anticipated. The FAA will have to develop the missed approach procedure for Runway 32, but it will likely be a turn to the south similar to that for Runway 22L. The missed approach point would be over the harbor at an altitude of 400 feet or higher.
68.	Please present a Community (sic) in 1999 (2000 would be better!) and in 2010 for each planning alternative. These should be presented both graphically and in the form of statistical tables. Arrivals and departures should be detailed separately. All affected towns within Rt. 128 should (sic) as well as S. Shore towns down to Scituate and Norwell. If towns are affected differently in their different parts, with one getting departures for instance, the parts should be broken out separately on the tables, which compare alternative future scenarios.	Appendix E of the Airside Project Draft EIS/EIR included detailed operations data by runway end for each fleet and each alternative. Data was listed separately for arrivals and departures, and separately for jet aircraft and non-jet aircraft. Appendix C of this Supplemental DEIS/FEIR contains the same detailed operations data for the new 2015 High RJ fleet.
69.	Please show data which would have approaches and departures in "over the water" designs and have planes no closer than 1.25 miles to mainland areas out to a distance of 10 DME. If claims are made that fewer people will be affected by noise, such claims should be specific and quantified.	Please see the response to question 58. Chapter 6 of the SDEIS presents noise-exposed population details by town or neighborhood for the 29M Low, 37.5M High and 37.5M High Regional Jet Fleets.
70.	Please show data that clearly demonstrates what factors have correlated with increases in operations efficiency (more passengers per op.) at other airports in the past. With this data, present Logan in relation to whatever key indicators are found and then revise the operations forecasts to reflect the new understanding.	See Chapter 3 of this Supplemental DEIS/FEIR for a discussion of demand management programs at other US and international airports.
71.	Request that the EIS and ROD include language that makes a commitment not to fan out departures from any runway as a means of increasing capacity. Commit to not reduce departure intervals below those now in use.	The Logan Airside Improvements do not propose any changes to existing ATC procedures or flight tracks other than Reduced Minimums and Unidirectional Runway 14/32.

#	Comment	Response
72.	The EIS should contain a side-by-side comparison of actual measured noise data and modeled data for each MPA noise monitoring station for each planning alternative. If under estimation of modeled vs. actual measured, we request a new noise modeling study which increases operational parameters until they show only non-systemic variation from measured data. Contours resulting from new data should be compared to previous contours.	It is not possible to have actual measured noise data for future scenarios and planning alternatives. However, Chapter 6 of this Supplemental DEIS/FEIR does contain data and a discussion of measured versus modeled noise for 1999 Logan operations. Massport has reported differences between measured and modeled sound levels in Logan Airport's various GEIRs and Annual Updates (now called the ESPR) for a number of years. Differences at close-in locations were significantly reduced in 1996 through modification of source levels to better account for over-water sound propagation and apparent use of higher engine power settings than are normally assumed in the noise model's database (Refer to Appendix F of the *Logan Airport 1996 Annual Update).* In 1998, differences between measured and modeled noise became even less when Massport upgraded its monitoring system and began to report noise caused only by aircraft -- a metric directly comparable to the DNL exposure levels predicted by the noise model. At sites having exposure levels of 60 dB or more, this improvement to the monitoring system brought measured and modeled DNL values to within 0.2 dB of each other (Refer to Chapter 5 of the *Logan Airport 1998 Annual Update*). Massport continues to investigate possible causes for remaining differences and continues to pursue FAA approval of noise model adjustments that would permit expansion of its sound insulation program to include the effects of terrain. Massport also expects to extend eligibility lines to include boundaries that follow local streets rather than strict noise contour lines. Nevertheless, Massport continues to believe that the FAA's INM noise model used in the Airside Project noise analyses accurately represents expected noise exposure.

#	Comment	Response
73.	The EIS should contain a map showing all sub-paths used to do noise modeling for jets for each arrival and departure. The map should show these paths in relation to geographic and political boundaries. Explain methods of selecting sub-paths and how they are validated. There should be a complete listing of modeled aircraft for each planning alternative and how choices were made. There should be also an explanation of what tests were used to validate the assumption that in noise modeling noise from over the water approaches should be boosted for operations below 1,000 feet but not for those over water at higher altitudes.	The darker lines in Figures 5.2-1 and 5.2-2 indicate the actual flight tracks used to model the operations for all scenarios involving the existing runway configuration. The darker lines in Figures 6.2-1 through 6.2-4 indicate the actual modeled tracks used to model all scenarios, which include the proposed new unidirectional Runway 14/32. In each case, tracks flown by jets are shown in yellow, turboprops are shown in purple. Arrivals are separated from departures. Political jurisdictions for all communities within approximately 20 miles of Logan Airport are outlined on the basemaps in these figures. The lists of aircraft modeled on these tracks and their frequency of occurrence are included in multiple tables in various appendices to the study documents. The aircraft types modeled for 1993 and for all the original 29M, 37.5M, and 45M High and Low scenarios were shown in Volume III, Appendix E, Table 11 of the Draft EIR/EIS (the "Blue Book"). The table lists annual operations by individual aircraft type; the noise model used these numbers of operations divided by 365 to get average daily operations. The frequency of occurrence for all of these flights were shown in Appendix H of the same document in the table labeled "Aircraft Operations by Fleet, Alternative, Runway End and Operation [arrival or departure]." The aircraft types modeled for all of the 1998 and 2015 High Regional Jet Scenarios are shown in Volume Two, Appendix C. In these cases, the operations are shown as average daily operations. Their frequency of occurrence by runway end is also shown Appendix C. Justification for the over-water sound propagation adjustments are included in a letter from Mr. Kenneth Eldred to Mr. John Gulding at the FAA's Office of Environment and Energy requesting approval to modify the INM database so as to improve the differences between measured and modeled noise exposure levels. The letter along with FAA's response is included in its entirety in Appendix C of the Interim Supplemental DEIS (the "Brown Book"). The changes are applicable to aircraft at low altitudes because over-water sound propagation differs from normal over-ground sound propagation only when an aircraft is low to the horizon and the noise emanating from it reflects off the acoustically "hard" surface of the water as opposed to being partially attenuated (lessened) as it passes over softer ground.
74.	Explain the geographic scope of the EIS. How was the study area determined? Was noise modeling used to determine it? If so, there should be a discussion of alternative	Chapter 5 of the Airside Project Draft EIS/EIR and this Supplemental DEIS/FEIR discuss in detail the geographic scope of the Logan Airside project. As described, the study area for each category of impact

#	Comment	Response
	methods for determining the study area not based on noise modeling.	varies. For example, noise impacts are examined in a number of ways including Day Night Sound Level (DNL) contours beginning with areas closest to the airport, the 75DNL out to the FAA's threshold of incompatibility at the 65DNL. In addition to this, and in response to the May 7, 1999 EOEA Certificate, Massport presented analysis out to the 60 DNL contour. Please refer to Chapter 5 for definition of the various study areas.
75.	Request that an appendix to the Brown Book, in which all tables, slides, and other graphics shown to the Garvey Panel, but not included in Brown Book, be published and distributed to the public.	Comment Noted. Please refer to Appendix A of this Supplemental DEIS/FEIR , which contains meeting minutes for all the SDEIS Panel meetings. These meeting minutes reflect the substance of all presentations made to the Panel as well as questions and answers that followed each presentation.
76.	Request that a study of steeper approach paths as a method of mitigating arrival impacts be done. It should include other airports in the US and abroad using such steeper paths.	Comment noted. The FAA requires that all new or relocated glideslopes be commissioned with the standard 3 degree slope. Steeper approaches can only be approved by Washington under exceptional circumstances. Foreign practices are not applicable in the US.
77.	The EIS should include an evaluation of the Airport Noise & Capacity Act of 1990, including a discussion from a qualified attorney about what alternatives will be available to future MPA management teams if they wish to modify or undo effects produced by the construction of 14/32, or if they wish to remove 14/32 from service.	Comment noted. Evaluation of the Airport Noise & Capacity Act is not part of this Supplemental DEIS/FEIR.
78.	The EIS should include a study identifying communities affected by jet operations from more than one runway.	The Draft EIS/EIR contains analysis of all communities within the 65 DNL, the FAA's threshold of incompatibility. In fact, at MEPA's request, the analysis extends to the 60 DNL. These contours contain all communities affected by one or more runways.
79.	Compare the experience they can expect with 14/32 in operation to the PRAS goals established for communities near the airport.	Refer to Chapters 4 and 6 of the Airside Project Draft EIS/EIR and this Supplemental DEIS/FEIR for a comparison of PRAS achievement for the Preferred Alternative and the No Action alternative.
80.	Request that a study be done to show, in NW winds, what other delays (en route, over-scheduling, and mechanical problems) are happening at that time? What is the %? This should be in the EIS.	Comment noted. Appendix D of this Supplemental DEIS/FEIR contains a case study of northwest wind delays. There are no data on all of the other delays that may randomly take place in northwest conditions. However, all of the delays identified in the Draft EIS/EIR as occurring in northwest winds are due to northwest winds, and not to other causes.
81.	Recommend that the "first come, first served process" be studied with respect to the possibility of changing it as a demand management technique	Discussions with the FAA Headquarters in Washington determined that this concept would require study on a national basis.

#	Comment	Response
82.	Since delay is a given at all airports, the CAC asks the FAA to determine, within the SDEIS process, "acceptable" delay at Logan.	See response to question 62.
83.	The CAC, through the Panel, requests that the FAA quantify and qualitatively present the complete, cumulative environmental impacts, as well as the total cumulative construction environmental impacts of the following: the proposed Runway 14/32, the proposed centerfield taxiway, the forecasted increase of ground transportation to and from Logan within a four mile radius of Logan, and the Central Artery project.	Chapter 7 of this Supplemental DEIS/FEIR discusses the cumulative environmental and construction impacts of the Preferred Alternative, which includes Runway 14/32 and all the proposed taxiway improvements, and all concurrent construction projects. The impacts of ground transportation traffic associated with each forecast passenger level are discussed in the *Logan Airport 1996, 1997, and 1998 Annual Updates*, and the *Logan Airport 1999 Environmental Status and Planning Report.*
84.	The CAC requests that the FAA rule that the impact of the proposed dramatic increase in air traffic that would be generated by Runway 14/32 over densely populated inner city, low income and minority communities is too significant to warrant FAA approval to construct this new runway.	Comment noted. Please refer to Question 36 for environmental justice.
85.	The CAC requests that the FAA engage "outside the box" professional transportation planners to bring alternative proposals to Runway 14/32 to the Panel table for consideration.	Comment noted.
86.	Has the direction of 14/32 changed? If so, how did it change and why?	The direction has not changed.
87.	Request from the Town of Hull Jet Noise Task Force that the FAA/MPA do a Part 161 study to obtain all the additional data it would produce.	Comment noted. A Part 161 analysis is not part of the scope for this Supplemental DEIS/FEIR.
88.	Request from the Bayswater neighborhood in East Boston that Panel support in the study of a higher blast fence and make it collapsible as well.	In December 2000, Massport filed an ENF to remove the blast fence because of aircraft safety concerns. Massport's analysis showed that the benefits of the blast fence to the Bayswater community are very minimal and better results could be achieved through mitigation. Massport provided funds to the Bayswater Blast Fence Committee (BFC) to hire an independent consultant to study Massport's proposal.
89.	The prediction of a threefold increase in flights departing Runway 27 brings a request from the Roslindale/Jamaica Plain neighborhoods that a noise monitor be placed in their area to record present noise impacts. They also request that an analysis of the readings from this microphone be analyzed and compared to the predictions for this runway if 14/32 is built. In addition this neighborhood wants to know how the information from this microphone would be	Massport will consider adding a permanent noise monitor in the vicinity of Jamaica Plain. If it is added, the data collected by the monitor will include metrics such as the annual average DNL represented by the noise contours of this study. However, as is the case with all of the permanent measurement sites, the measured levels are not incorporated directly into the INM; rather, the results are compared to modeled levels to check for potential inconsistencies and to improve INM inputs when it is determined that the measurements highlight a problem with the noise modeling. In the past, such

#	Comment	Response
	incorporated into the INM and what the difference, if any, in the description of the neighborhood noise would be.	inconsistencies have led Massport to modify its noise model to account for over-water sound propagation and, more recently, to include the effects of terrain in Orient Heights.
90.	From the City of Cambridge comes the request to research the implications of the statement: "Increase the aircraft size, decrease the frequency."	Comment noted. All of the forecasts used in the Draft EIS/EIR reflect an increase in average aircraft size over time.
91.	In Charlestown a question about the reliability of the predictions that 37-45 million passengers would be handled at Logan in the future. How reliable is this information? On what do you base this information?	To accommodate uncertainty, a wide range of future passenger and activity forecasts have been studied in the Logan Airside Project. This includes Logan's actual activity levels achieved in of 1993 and 1998, as well as 12 different levels in the future (with and without Peak Period Pricing). The forecasts are discussed in Chapter 4 of this Supplemental DEIS/FEIR and in Appendix E of the Airside Project Draft EIS/EIR. The uncertainty is not so much the future level of passengers, but when that volume will occur.
92.	From Braintree comes a request that the PRAS system be reevaluated before the expansion proposal proceeds. The feeling is that the PRAS has not achieved the goals all these years. The feeling is that the FAA didn't use the PRAS system whenever possible all these years. So, on what basis is the public in impacted communities to believe that the PRAS system will ever be used in future?	The proposed Unidirectional Runway 14/32 provides controllers with the ability to redirect more aircraft over water and away from people. Regardless of the noise policy, arrivals and departures over water would be desired. Runway 14/32 provides the tower with the ability to better achieve the PRAS goals by providing a third runway in the NW direction. If the tower can maintain capacity in all directions, they will be more likely to change runway configurations more frequently, which is the very foundation of PRAS. Section 4.3 of the Supplemental DEIS contains a detailed discussion of PRAS development and improvements, and of the FAA's increased conformance with the PRAS goals.
93.	A question on the INM input from the Town of Hingham: How is the data put into the INM and how is it verified? The question comes because there are noted differences between the on-site microphones and the Integrated Noise Model read-outs in Hull, East Boston, and Chelsea. Please research and respond to this in the DEIS.	The INM essentially utilizes flight tracks and the aircraft operations on them to compute noise at points on the ground. Existing flight tracks are generated directly from plots of radar data obtained from the FAA's air traffic control tower that are compiled by Massport's permanent noise and operations monitoring system. The specific aircraft types and the frequency with which they occur on the tracks are also determined from radar records generated by the monitoring system. Details of this data collection effort are summarized each year in Massport's *Environmental Planning and Status Report* (formerly known as a *Generic Environmental Impact Report*) for Logan Airport. Those annual documents have also addressed differences between measured and modeled DNL levels at the measurement sites around the airport. Though differences should always be expected to occur to some degree (due to factors such as pilot technique in flying

#	Comment	Response
		an aircraft, or non-standard atmospheric conditions), significant improvement in the differences between measured and modeled noise exposure was achieved when Massport upgraded its system in 1997 to report aircraft-only DNL as opposed to total DNL which includes the additional effects of non-aircraft noise. For example, in 1998 the difference between measured and modeled DNL due to aircraft was only 1.1 dB at site 26 in Hull, was 2.2 dB at site 15 in Chelsea, and ranged from -0.3 to 1.3 dB to 2.9 dB at the Jeffries Point Yacht Club, East Boston High School, and Bayswater Street at Annavoy in East Boston.
94.	In Chelsea there is an observation and a request. They believe that the "flaws" in the noise monitoring system are not researched and resolved in an adequate fashion in the document. But on issues of delays there are loads of statistics and analysis. They therefore believe that there are huge gaps on existing documents. And there will be unfair and inexact conclusions if the analysis information gap continues into the new document. Please address and resolve these gaps.	See responses to question 72 and 93.
95.	From Chelsea again a response to this statement is sought: "All growth must be accommodated." Please address this philosophy.	This comment is not attributable to the Airside Improvements Project or any Airside environmental documents. The Preferred Alternative provides delay reduction benefits at current operation levels and does not add capacity to the airport. Runway 14/32, which is part of the preferred alternative, allows Logan to maintain a 3-runway configuration in Northwest winds. See the analysis in Chapter 4 of this Supplemental DEIS/FEIR that quantifies 1998 delays at Logan and the delay reduction that would have been achieved if Runway 14/32 was available in 1998.
96.	In the City of Everett, the Council and several citizens requested an additional noise monitor to establish present noise impacts. So far this request has not been granted by the MPA. Their concern to the Garvey Panel is that present noise is being underrepresented from a threefold increase from Runway 33 departures and will be under-counted as well. Please analyze and respond to this issue.	A noise monitor is located in Everett on Tremont and Prescott Street that provides adequate noise monitoring data.
97.	People in Revere and the Orient Heights neighborhood of East Boston, and in Winthrop as well, want a presentation on the impacts of the Centerfield Taxiway and the changes on the landing minimums. They are	Revere, East Boston, and Winthrop all have representatives on the CAC. The CAC has been fully briefed on all aspects of the Airside Project. In addition, two public hearings on the Draft EIS/EIR were held, as well as meetings in each community to review the

#	Comment	Response
	very concerned that the true impacts of these proposals are not being disclosed and fully evaluated from a neighborhood perspective. Please respond. Please respond by having a meeting in the affected neighborhood.	project.
98.	The Somerville Airport Expansion Group asks that at the October meeting a presentation be made about the design of the runway surface and runway safety areas at each end of the proposed Runway 14/32. They want to know about displaced thresholds and landing distance available. They want to know what the glide slope and minimums will be. They want to know at what point missed approaches abort 14/32 landings.	Runway 14/32 has a landing distance of 5,000 feet with a Runway Safety Area of 1,000 feet on either end, and no displaced threshold. The FAA requires that all new glideslopes be set to 3 degrees. The IFR decision height is anticipated to be 400 feet, with a visibility minimum of ¾ mile.
99.	Why does the SDEIS show a waiver of FAA standards on safety on the proposed 14/32? The Cohasset Airport Study Silence (sic) believes that the FAA safety standards will be waived by the cutting off a corner of the runway safety area on the 14 end. How can they allow this when safety standards are FAA's stated top priority? Why not shorten the runway safety area? Should an accident happen within that officially truncated safety area wouldn't the FAA be responsible?	Chapter 3 of the Supplemental DEIS describes the proposed layout of Runway 14/32 and the associated Runway Safety Areas. The RSA on the approach end of Runway 32 will be a full 1,000 feet in length, but will have the corners trimmed slightly to avoid filling the harbor. A preliminary analysis by the FAA confirms that the RSA will provide an acceptable level of safety.
100.	From South Boston comes the request that the FAA include in the SDEIS the impacts the building heights planned for South Boston waterfront projects would have on Runway 27 departure usage. How would that negate any delay reduction benefits of Runway 14/32?	No known development plans in South Boston will require an increased climb gradient for Runway 27 departures. Any new development plans will be subject to a FAR Part 77 airspace evaluation by the FAA, which will not approve any additional restrictions on Logan operations. Nearly all aircraft operating at Logan exceed the current Runway 27 climb gradient by a wide margin. Moreover, this restriction applies only under IFR conditions, and Runway 27 and 32 will only be used together under VFR conditions.
101.	Does the INM take into account low frequency noise impact?	The A-weighted sound levels utilized by the INM include noise within the frequency range normally considered low frequency (25 to 80 Hz) but those frequencies are de-emphasized by the A-weighting because our ears are less sensitive to acoustic energy in those bands; there has been no special treatment of low-frequency noise metrics in these analyses.
102.	Does the INM depict the noise, which occurs directly behind the aircraft?	Yes.
103.	Does the INM take into account bad weather conditions that cause noise impacts to be worse than on a standard day? Do any weather conditions get reflected in the INM?	No. The INM only addresses average local temperature and airfield elevation to the extent that those parameters affect sound propagation. The model has no provision for accommodating bad weather days, strong winds,

#	Comment	Response
		temperature inversions, or similar non-standard conditions.
104.	Does the INM measure sideline noise as the aircraft rolls down the runway?	Yes.
105.	Has there been an in-depth federal study to show how noise impacts affect the health of people who live near airports? If so, where and what are the results?	No, although there have been Federally sponsored reviews of literature on the health effects of noise and a number of international conferences on the subject. To date, there has been no conclusive evidence from this body of work to indicate a link between noise exposure levels in the community and related health effects. Nevertheless, to the extent that high exposure levels have any detrimental effects on people, the Preferred Alternative does more to reduce these high levels than any other alternative considered in this analysis.
106.	Has there been a study that reflects how an airport affects a neighborhood's overall quality of life? Little things like talking on the phone, watching television or just trying to hold a conversation can at times be very difficult when you live close to an airport.	Yes. Among the earliest of such studies is the EPA's report on "Levels of Environmental Noise Requisite to Protect the Public Health and Welfare with an Adequate Margin of Safety". The report addresses factors such as speech and sleep interference and considers public welfare to include such issues pertaining to quality of life. That document identified a DNL level of 60 dB as requisite to protect public health and welfare and a DNL level of 55 dB to include the margin of safety. However, the document was also careful to point out that EPA was not identifying a standard nor was it taking into account the technological or economic feasibility of achieving the identified levels.
107.	Although the document says there won't be any noise increase over the Boston Harbor Islands with the possibility of simultaneous arrivals on 33 and 32, how is this possible?	Section 6.3.3 of the Interim Supplemental DEIS was incorrect in stating that there are no increases in exposure over the Boston Harbor Islands under the Preferred Alternative. There are small increases estimated to be on the order of 1 to 3 dB depending on location within the Harbor. This Supplemental DEIS/FEIR is corrected to reflect this observation.
108.	The document includes less sleep disturbance in the preferred alternative. How can that be if triple the amount of operations fly off of 27 and triple the current amount of departures off of 33?	The Preferred Alternative causes an overall reduction in noise exposure by reducing aircraft delays and the number of daytime flights that are delayed into the night. In calculating total noise exposure nighttime jet operations (occurring between 10:00 PM and 7:00 AM) have a 10 times penalty to reflect the fact that nighttime noise is more disruptive.
109.	"Over the water" is a term most disputed in the South Shore. Their interpretation of the printed flight tracks combined with their experiential knowledge of observing the flight tracks has them conclude that planes are not flying "over the water" and will not fly "over the water" in the future. Please respond.	Aircraft on straight-in arrival tracks to the Runway 32 and 33 ends fly over water longer before overflying communities in the South Shore than aircraft arriving to any other runway end. Please refer to the Flight Tracks presented in Chapter 6 of this Supplemental DEIS/FEIR. The tracks have been expanded to cover a broader geographic area and include altitudes.
110.	There needs to be an environmental review	The PRAS goals were established by the PRAS

#	Comment	Response
	done on the PRAS so that all new information is shared with the public.	Advisory Committee, which consisted of representatives from Massport, the FAA, the airlines, and 12 neighboring communities. Massport's Preferred Alternative (Alternative 1A) mitigation program includes additional PRAS reporting requirements recommended to enhance the monitoring efforts. (See Chapter 4 of this Supplemental DEIS/FEIR.)
111.	It is necessary to have presented in terms lay people might understand the theory that the noise impacts generated by a threefold increase in departures on 27 and 33 are not significant or are even less than present use. Describe the reasoning behind the theory and how it is computed in recording the noise and drawing the contours and the impacts on the communities.	See response to question 108.
112.	Across from the Bayswater Street neighborhood there is a blast fence. This helps to reduce some impact from operations on the 22's. Will the Port Authority/FAA try again to remove the blast fence? What impact does the blast fence have on the proposal to reduce the landing minimum on 22 arrivals?	In December 2000, Massport filed an ENF to remove the blast fence because of aircraft safety concerns. Massport's analysis showed that the benefits of the blast fence to the Bayswater community are very minimal and better results could be achieved through mitigation. Massport provided funds to the Bayswater Blast Fence Committee (BFC) to hire an independent consultant to study Massport's proposal. MEPA held a public hearing in January 2000 and the public comment period was extended through February 9, 2001. Massport received a MEPA Certificate on February 23, 2001 stating that no additional environmental analysis was required.
113.	It is necessary to have more information about the Centerfield Taxiway and its relationship to gateholds and capacity. From a community perspective it seems that the airlines and airport would move passengers from the terminal onto planes, then have the planes move onto the much longer taxiway to park and wait for take-off openings. This gives the impression that delays are being addressed but it puts more aircraft in between two communities for longer times. Noise and pollution impacts on East Boston and Winthrop need to be re-evaluated and reviewed by people in these close-in neighborhoods and by the FAA and Massport.	Section 3.3.1 of the Supplemental DEIS describes the operational benefits of the Centerfield Taxiway. It will reduce taxiing delays for arriving and departing flights, and will reduce the number of aircraft queued up in the northern sector of the airfield. The Centerfield Taxiway will be an active operations area of the airfield and therefore not available to use as an overflow parking area as suggested by the question. It will have no influence on airline schedules, which are limited by the gates available at Logan terminals.
114.	On the South Shore there is an issue with the noise as recorded on the microphone at the high school. What is a sample of the recorded noise there over a period of time? How does the actual recording of the noise jibe with the INM model? How many times	Since the late-1997 upgrade to Massport's permanent noise monitoring system, aircraft-only DNL sound levels have been measured continuously 24 hours a day, 7 days a week, 365 days a year at Hull High School and other sites surrounding Logan Airport. The data are presented as annual average values and have been reported in the

#	Comment	Response
	is the noise measured at over 60 dB? How does the noise measurement correlate with the flight track usage?	1998 Annual Update to the Logan Airport Generic Environmental Impact Report (GEIR) and the 1999 Environmental Planning and Status Report (ESPR). At Hull High School, in particular, the difference between these measured values and the INM-generated noise contours that are also produced in conjunction with these documents were 1.1 decibels in 1998 and 0.6 decibels in 1999. In each case, the measured levels were slightly higher than the modeled contours; however, these differences are considered small and represent extremely good correlation between measured and modeled noise exposure. Measurement data have not been examined further to identify how many times the sound level has exceeded 60 dBA.
115.	From the South Shore is a request to describe the so called "over the water" track. Exactly when and how does the plane fly over water? How low and how often does the track take the planes over populated areas? Please show moving computer graphics to demonstrate the flight tracks over the South Shore.	Aircraft on straight-in arrival tracks to the Runway 32 and 33 ends fly over water longer before overflying communities than aircraft arriving to any other runway end. Please refer to the Flight Tracks presented in Chapter 6 of this Supplemental DEIS/FEIR. The tracks have been expanded to cover a broader geographic area and include altitudes.
116.	From Winthrop comes the question about Sunday morning heavy odor and constant revving sound. Why does this happen?	The temporal data indicate less jet and turboprop aircraft activity on Sunday mornings than weekday mornings and, in most cases, Saturday mornings. However, it is possible that on Sundays, residents of Winthrop are more likely to be out-of-doors working around the house, playing, or reading the newspaper. Mornings are also the worst time for atmospheric inversions. The combination of these two latter factors could result in these neighbors noticing the odors and noise more on Sunday mornings than on others. The source of the "constant revving sound" on Sunday mornings is unknown.

Amtrak Memorandum Regarding Ridership Projections
for Acela Service

HARRIS

MEMORANDUM

TO:	Beverly Jones, SH&E	**DATE:**	January 8, 2001
FROM:	Joanne Haracz	**RE:**	Amtrak Ridership Projections

This memo documents my January 8, 2001 phone conversation with Russ Hall of Amtrak regarding the current status of ridership projections for Acela service on the Northeast Corridor. Mr. Hall informed me that new ridership projections were underdevelopment, but were not publicly available at the current time.

National Railroad Passenger Corporation, 30th and Market Streets, Philadelphia, PA 19104

Joanne Haracz, AICP
Planning Department Manager
Frederic R. Harris, Inc.
66 Long Wharf
Boston, MA 02110

Dear Ms. Haracz:

Thank you for you recent letter inquiring about the availability of ridership projections for Amtrak's *Acela Express* and *Acela Regional* service. Specifically, you requested information about projected station boardings and alightings, estimated ridership between New York and Boston, fare structure and details of the operating plan for Acela service.

You may be aware that the manufacturers of the high-speed trainset recently informed Amtrak of a delay in the delivery of the new trainsets for the *Acela Express* service. For that reason, the operating plans for *Acela Express* and *Acela Regional* service are still being refined. The operating plan is an integral component in preparing projections of ridership, and any projections based on interim plans would be unreliable for planning purposes.

I regret that we cannot provide you with specific information you have requested. I encourage you to contact me in the coming months when we may be better able to provide some of data you requested. You can reach me at (215) 349-3324.

Sincerely,

Nicole Seitz
Government Affairs Officer

AN EQUAL OPPORTUNITY EMPLOYER

ENVIRONMENTAL IMPACTS OF INCREASED TRAFFIC AT REGIONAL AIRPORTS

INTRODUCTION

The Secretary of the Massachusetts Executive Office of Environmental Affairs (EOEA) and the Massachusetts Department of Environmental Protection (DEP) have expressed the need to understand the environmental impacts of increased growth at the regional airports. However, the Secretary also acknowledged the difficulties of presenting cumulative impacts for physically unrelated projects located in different states and in different stages of the planning and environmental review processes. In light of these difficulties, the Secretary specifically directed Massport to summarize the environmental impacts of the regional airports, as they have been described in existing environmental documents and reports.

DOCUMENTS REVIEWED

Massport collected and reviewed the latest available documents for the principal regional airports surrounding Logan, i.e., Manchester, T.F. Green, Worcester and Hanscom Field. The available environmental studies done for Manchester and T.F. Green were completed prior to the entry of Southwest Airlines and other low-fare carriers at those airports. Nevertheless, the reported impacts give an indication of the degree of environmental exposure that results from growth at these airports.

Table 1 - Available Environmental Documents for the Regional Airports

Airport	Lead Agency	Document	Principal Proposed Actions	Base Year	Base Year Activity	Analysis Year	Analysis Year Activity
Manchester	FAA	Final Environmental Impact Statement, Manchester Airport Master Plan Update, June 1997	• Reconstruct and Lengthen Runways • Expand Terminal Building (+23 aircraft parking positions) • Improve Ground Access • Build New Parking Garage	1995	Operations: 85,257 Passengers: 902,000	2015	Operations: 155,500 Passengers: 3,380,000
Providence	Rhode Island Airport Corporation	Final Master Plan Update, T.F. Green State Airport March 1999	• Construct new parallel taxiways for Rwys 5R-23L • Construct Runway 34 Holding Apron • Regrade RSA beyond 34 end of Runway 16-34 • Pavement rehabilitation for Rwy 16-34 • Rwy 16 threshold displacement • Relocate Taxiway K • Removal of Hangar 1	1993	Operations: 122,588 Passengers: 2,373,000	2015	Operations: 137,115 Passengers: 5,367,150
Worcester	FAA	Final Supplemental Environmental Impact Statement/Report, Worcester Airport – 5 Year Plan of Improvements, December 1995	• Construct parallel taxiway for Rwy 11-29 • Reconstruct Rwy 15-33 and RSA's for 15-33 • Realign taxiways • Reconstruct terminal apron	1993	Operations: 73,195 Passengers: 191,472	1998	Operations: 78,147 Passengers: 232,736
Hanscom	Massport	Hanscom Field 1995 GEIR Update, April 1997	*No Physical Improvements Studied* *The HGEIR analyzed various scenarios of future growth including a 3% AAG with Regional Commuter Service*	1995	Operations: 190,282 Passengers: 5,228	2010 "3% Growth Scenario with Regional Commuter Service"	Operations: 296,500 Passengers: 216,906

SUMMARY OF DOCUMENTED ENVIRONMENTAL IMPACTS

Manchester Airport

Table 2 – Summary of Environmental Impacts of Preferred Alternative for Manchester Airport Final Environmental Impact Statement

Impact Category	Impacts
Noise	• Projected area within the DNL 65dB contour for the Proposed Action is 2.97 square miles compared to 4.58 square miles in 1995. • Noise exposed population is projected to decline from 6,575 in 1995 to 2,270 in 2015. After 34 homes are purchased, the noise exposure for 2015 is 1,044 people.
Social Impacts	• The acquisition of several properties is necessary for the construction of proposed access road improvements and Runway 6/24 reconstruction. Total acquisition of 117 properties: 97 residences; 2 commercial properties; 18 vacant parcels and a church, school and day care center.
Air Quality	• Locally, CO, VOC and NO_x increase under the preferred alternative. Projected emissions are within the de minimis levels of EPA's General Conformity regulations. • Regionally, there is an air quality benefit since greater use of Manchester translates into fewer passengers driving to Logan Airport and hence fewer vehicle miles traveled (VMT's) in the region. In 2015, regional emissions would be reduced as follows: CO –17.8%; VOCs –16.7%; and NO_x –12.3%.
Water Quality	• Preferred Alternative may potentially affect both groundwater and surface water quality. • Impacts to groundwater resources may occur due to a reduction in recharge caused by an increase in impervious surfaces. • Increased amounts of glycol-based deicing fluids may result in high BOD discharges to Little Cohas Brook. • No substantial changes in the quantity of stormwater run-off due to reconstruction and upgrading of stormwater drainage system.
Section 4(f) and 6(f) Parklands	None
Historic and Archaeological Resources	• The Preferred Alternative would impact 4 of 5 historic archaeological properties identified as eligible for the National Register of Historic Properties and 7 of 9 sites considered sensitive for prehistoric archaeological resources.
Ecosystems	• 13.02 acres of wetlands would be affected by fill and stream relocation associated with the Preferred Action. 11.52 of these acres are associated with the extension of Runway 17/35 and the relocation of Little Cohas Brook. • Impacts to the Little Cohas Brook habitat include relocating the stream and filling existing wetland habitat. Direct impacts are expected to occur to the resident species and less mobile species, while the indirect impact would be limiting wildlife access to the stream. • No significant impacts to the bald eagle, a federally-protected species. • Minor impacts to the state-listed endangered species, the upland sandpiper, will be mitigated. • Two state-protected flora species of special concern, the single mountain laurel plant and a few clusters of trailing arbutus in the vicinity of Little Cohas Brook, would be affected. However, these occur on airport property and therefore mitigation is not required.

T.F. Green/Providence Airport

The last Environmental Impact Statement (a State document) for the T.F. Green Airport was for the Terminal Area Plan and was completed in 1990. A more recent planning document, the Final Master Plan Update, was completed in March 1999. The Final Master Plan Update provides an environmental overview that identifies potential significant environmental impacts of planned development projects at T.F. Green Airport. Those potential impacts are summarized below.

Noise

The proposed improvements in the 1999 Master Plan Update are not expected to significantly change noise patterns or the number of affected areas since no new runway development is proposed. The most recent Noise Exposure Maps for T.F. Green, which were prepared for 1993 actual and 1998 projected operational activity were approved by the FAA in April 1995. A Part 150 Noise Study was recently completed.

Table 3 - T.F. Green Baseline 1993 and Forecast 1998 Noise Impacts of DNL 65 dB and Greater

	1993	1998	Change
Total Area (sq. mi.)	3.15	3.03	-3.8%
Off-Airport Area (sq. mi.)	2.09	1.99	-4.80%
Number of Dwellings	2,170	2,065	-4.7%
Number of Residents	5,890	5,600	-5.0%

Source: Wyle Research report WR 94-19m revised Noise Exposure Maps for T.F. Green State Airport, April 1995.

Table 4 - Overview of Potential Environmental Impacts of 1999 T.F. Green Airport Master Plan Improvements

Impact Category	Impacts
Compatible Land Use	• Master Plan improvements are not expected to significantly change the compatibility of land use within the airport vicinity.
Social Impacts	• None
Air Quality	• The T.F. Green Airport lies within the Metropolitan Providence Interstate Air Quality Control Region (AQCR). This AQCR, as well as the entire state of Rhode Island, has attainment status for all of the primary pollutants, except ozone (O_3). The Rhode Island Department of Environmental Management (RIDEM) currently inventories emissions in the area for hydrocarbons (HC), nitrogen oxides (NO_x), and carbon monoxide (CO), and has found these pollutant levels to be within attainment standards. • There appear to be no improvements resulting from the Master Plan Update that would significantly affect the air quality in the Airport vicinity.
Water Quality	• It is anticipated that the future Taxiway K relocation and the planned grading of the RSA at the approach end of Runway 34 will require a Water Quality Certification because these planned improvements may impact Federal or State jurisdictional wetland areas.
Section 4(f) and 6(f) Parklands	None
Historic and Archaeological Resources	• The planned grading of the RSA at the approach end of Runway 34 will require an archaeological assessment since the project is located near the Warwick Pond area. According to the Rhode Island Historical Preservation and Heritage Commission the Warwick Pond area may contain areas of archaeological significance.
Biotic Communities	• The grading of the RSA at the approach end of Runway 34 and the relocation of Taxiway K would most likely impact biotic communities, primarily vegetated wetlands and other natural vegetated areas. The effects on biotic communities will be addressed during the preparation of an Environmental Assessment.
Wetlands	• It is anticipated that the planned grading of the RSA at the approach end of Runway 34 and the relocation of Taxiway K will impact state and/or federal wetlands and/ or buffers. Potential impacts may require mitigation.
Floodplains	• It is anticipated that the planned grading of the RSA at the approach end of Runway 34 and the relocation of Taxiway K will impact land area in the 100-year floodplain as designated by the Federal Emergency Management Agency (FEMA).

Worcester Airport

Table 5- Final Supplemental Environmental Impact Statement/Report – Worcester Airport 5 Year Plan of Improvements

Impact Category	Impacts
Noise	• None of the proposed projects in the 5 Year Plan affect airport noise contours.
Water Quality	• Projects are have an overall long-term beneficial impact on the quality of water draining from the airport.
Air Quality	None
Wildlife Habitat	• A grassland management program was developed for the airport in cooperation with the Massachusetts Division of Fisheries and Wildlife. It was implemented in 1995 to enhance wildlife habitat for grassland species of birds.
Traffic	• A traffic analysis of several intersections in the vicinity of the airport indicated no adverse impacts as a result of the 5 Year Plan improvements.
Section 4(f) Properties	None
Historic and Archaeological Resources	None
Biotic Communities	None
Wetlands	• Construction of the parallel taxiway to Runway 11-29 will require the unavoidable filling of 4.2 acres of wetland resources. Wetland replication on a greater than one-to-one basis was proposed for mitigation.
Floodplains	• Construction of the parallel taxiway to Runway 11-29 will require the filling of approximately 2 acres of floodplain.

Noise

The City of Worcester conducted a Part 150 Noise Study of the Worcester Airport from 1989 to 1991. A summary of the noise impacts from the Noise Exposure Map is presented below.

Table 6 – Summary of Worcester Noise Exposure Map Impacts

	Base Year 1989			Forecast Year 1994		
	60-65 dB	65-70 dB	70+ dB	60-65 dB	65-70 dB	70+ dB
Area (acres)	460	50	0	1094	337	7
Dwelling Units	23	0	0	216	1	0
Population	60	0	0	571	3	0

Hanscom Field

As directed by the EOEA Secretary, the 1995 Hanscom Field GEIR Update provided detailed 1995 baseline conditions at and around Hanscom and identified hypothetical future operations and land use scenarios and associated environmental impacts for forecast 2000 and 2010 operations. The environmental impacts of aircraft operations for the 2010/3% Growth scenario, which assumed robust growth in scheduled regional commercial services, are summarized below.

Table 7 – Summary of Environmental Impacts of Aircraft Operations for the Hanscom Field 2010/3% Growth Scenario

Impact Category	Impacts
Noise	• Significant increase in noise exposure due to predicted increased military operations. • 31 homes are predicted to be exposed to Day-Night Average Sound Levels greater than 65dB. • Total noise exposure from departures is predicted to increase from 114.0 in 1995 to 115.6 in 2010/3% Growth Scenario.
Air Quality	• Predicted aircraft and motor vehicle emissions are higher than in the 1995 Baseline due to (1) a shift in the fleet mix from single-engine piston aircraft to turboprops, jets and helicopters; (2) the increase in total operations; and (3) additional predicted roadway traffic. • Total emissions increase from 4.0% to 9.1% per year, depending on the pollutant. However, total Hanscom Field emissions remain small compared to total emissions for Middlesex County. • Hanscom is predicted to remain in full compliance with the National and Massachusetts Ambient Air Quality Standards (NAAQS) and the MA DEP 1-hour NO_2 Policy Guideline.

New England Governors' Conference Resolution Furthering the Regional Transportation System

The Commonwealth of Massachusetts
Executive Office of Transportation and Construction
Ten Park Plaza, Boston MA 02116-3969
Office of the Secretary

Argeo Paul Cellucci
Governor

Jane Swift

Commissioner James Sullivan
Department of Transportation
2800 Berlin Turnpike
Office of the Commissioner
Newington, CT 06131-7546

Dear Commissioner Sullivan,

On behalf of Governor Cellucci and Lt. Governor Swift, we are pleased to invite you to join New England's transportation leaders for the first quarterly meeting of the New England Regional Transportation Coordinating Council on February 16, 2001 at 1:00 at Worcester Union Station Worcester, Massachusetts.

At the most recent New England Governors Regional Transportation Summit, the Governors agreed to establish the Council to oversee, guide, and implement regional policies and initiatives. Our cooperative efforts will help create an even more efficient regional intermodal system that continues to support New England's participation in the global economy. A copy of the resolution is attached.

We expect the Council meetings will be held once every quarter, as is contemplated in the resolution, and this first meeting will be an organizational meeting to establish the goals of the Council and a timeline for achieving our objectives.

We look forward to seeing you on February 16th. Please let Siobhan Perenick, at 617-973-7013, know who will be attending the meeting with you.

Regards,

Kevin J. Sullivan

NEW ENGLAND GOVERNORS' CONFERENCE, INC.

RESOLUTION NUMBER 154

A Resolution of the New England Governors' Conference, Inc. Furthering the Regional Transportation System

WHEREAS, New England's Governors recognize that an integrated regional transportation system is fundamental to the economic, social, and environmental well-being of the New England States; and

WHEREAS, New England is a unique region fully participating in the global economy and sharing a highly skilled workforce that is more mobile than ever; and

WHEREAS, the development of an efficient intermodal regional transportation system that maximizes options, increases connections and continues to promote economic growth is a priority of the New England Governors' Conference, Inc.; and

WHEREAS, New England has been engaged in regional transportation planning for the past decade and there is now emerging a New England Regional Transportation System; and

WHEREAS, the New England states can build on this transportation network to create an even more efficient regional intermodal system that continues to support New England's participation in the global economy.

NOW THEREFORE BE IT RESOLVED THAT the New England Governors' Conference, Inc. will

Re-establish the New England Governors' Conference, Inc. Regional Transportation Coordinating Council, with two members appointed by each Governor. This body will meet quarterly to oversee, guide and implement regionalization policy and initiatives;

Petition Congress to provide dedicated funding to support New England's regional transportation planning efforts and invite the federal transportation agencies to participate as members of the New England Governors' Conference, Inc. Regional Transportation Coordinating Council; and

Governor JOHN G. ROWLAND Connecticut | Governor LINCOLN C. ALMOND Rhode Island | Governor ANGUS S. KING, JR Maine | Governor ARGEO PAUL CELLUCCI Massachusetts | Governor JEANNE SHAHEEN New Hampshire | Governor HOWARD DEAN, M.D. Vermont

Petition the US Department of Transportation to work with the Congressional delegation to declare New England a "unique" region in order to allow regulatory flexibility in applying federal transportation policy; and

BE IT FURTHER RESOLVED THAT The New England Governors Conference, Inc. agrees that the New England transportation agencies, along with the Federal Aviation Administration, will embark on the next phase of study, which will evaluate ways to:

Increase domestic and international air service at the regional airports;

Increase non-scheduled charter service and air cargo activity at the regional airports;

Increase HOV/ground transportation and rail alternatives to service the regional airports; and

Develop an air service action plan for the regional airports.

AND BE IT FURTHER RESOLVED THAT The New England Governors' Conference, Inc. also agrees that its Regional Transportation Coordinating Council will:

Survey regional passenger hubs and strive to reduce the differences that passengers experience in making a trip via a combination of local and inter-city transit systems (i.e., local bus, subway and inter-city rail or bus) by developing compatible passenger information systems, including:

door to door web based transit trip planning
consistent signage and electronic information at stations and terminals
locating traveler conveniences such as visitor information centers,
ATMs, and on-site ticket sales for connecting modes

Encourage long distance travel options by investing in new systems for remote check in and luggage transfers between train, bus and air;

Cooperate to integrate New England's transit and turnpike systems by integrating the fare collection and toll technologies;

Study opportunities to improve the regional rail system, including safe and convenient passenger service on the region's designated high-speed rail corridors;

Maintain the states' commitment to enhance the accessibility of the regional system through station design and equipment choice, including lift equipped inter-city buses and information systems for the hearing impaired and the visually impaired;

Establish a New England Intermodal Freight Alliance to analyze key freight corridors in and through New England, including the way that freight and passenger systems share a single corridor;

Identify physical constraints, environmental benefits and market opportunities for each corridor and mode;

Investigate different forms of public-private partnerships to enhance the freight system and assure adequate and continuing maintenance and upgrades;

Offer technical assistance to local planners to identify and prioritize projects that will increase the efficiency of the freight system while respecting residential neighborhoods;

Work with the travel industry to tie the regional airports into the reservation system of travel agents and Internet sites when visitors are looking to access New England; and

Explore the creation of an electronic database (New England Regional Ground Access System) containing schedules of all modes of transportation to the region's airports.

ADOPTION CERTIFIED BY THE NEW ENGLAND GOVERNORS' CONFERENCE, INC. ON FEBRUARY 27, 2001.

Governor John G. Rowland
Governor of Connecticut
Chairman

Overview of Proposed New England Airport System Study Update – February 2001

FAA Regional System Plan Update

- Introduction/Background
- Study Purpose
- Study Background
- Study Organization
- Major Issues
- Study Structure/Content
- Public Consultation
- Schedule

FAA Regional System Plan Update

Introduction/Background

- Evolving roles of New England airports within the regional aviation system.
- Growing aviation demand due to increases in income, lowered fares, and changes in the travel patterns of our lives and occupations.
- The FAA recent forecast of an additional 23 million annual passengers above current levels within the New England region by 2010.

FAA Regional System Plan Update

Introduction/Background (continued)

- Need to identify opportunities that may exist to further enhance the operation of New England's regional system of airports, including an examination of the potential of other transportation modes to either provide alternative services.

- Interest raised through the ongoing *Logan Airside Improvements Planning Study*. A consistent theme of comments on this project has been that improvements at Logan Airport should be considered within the context of regional transportation planning.

FAA Regional System Plan Update

Study Purpose

Provide the background and analytical framework for a common understanding of:

- The current and future demand for aviation services across the New England Region,
- The roles of the major scheduled passenger service airports,
- The inter-relationships of those roles on the system,
- The constraints and challenges that will be faced by current patterns of service, and
- The identification of policies, strategies and infrastructure that would enhance system performance.

FAA Regional System Plan Update

Study Background

- Boston Regional Airport System Study *(1989)*
- Second Major Airport (SMA) Study *(1990)*
- Strategic Assessment Report (SAR) *(1993)*
- New England Transportation Initiative (NETI) *(1995)*
- New England Regional Air Service Study *(1995)*

FAA Regional System Plan Update

Regional Airports in 1995 Study

State	*City*	*Airport*	
Connecticut	Hartford	Bradley International Airport	(BDL)
	New Haven	Tweed-New Haven Airport	(HNV)
Maine	Bangor	Bangor International Airport	(BGR)
	Portland	Portland International Jetport	(PWM)
Massachusetts	New Bedford	New Bedford Regional Airport	(EWB)
	Worcester	Worcester Regional Airport	(ORH)
New Hampshire	Manchester	Manchester Airport	(MHT)
Rhode Island	Providence	T.F. Green State Airport	(PVD)
Vermont	Burlington	Burlington International Airport	(BTV)

FAA Regional System Plan Update

Study Organization

- **Project Administration Group**. Massport and the State of Massachusetts would be the financial sponsors of the FAA grant. Massport would manage the grant and provide all administrative functions.
- **Project Management Team**. Six state aeronautical agencies and a representative from the hub airports. Project Management Team would be signatories of a Memorandum of Understanding (MOU) that would outline the guiding principles for the undertaking of the project. MOU would generally follow the MOU executed for the 1995 Regional Air Service Study.
- **Advisory Group**. Established to provide a forum for information sharing and peer review . Composed of a broad range of aviation and transportation technical specialists that would bring additional industry knowledge to the process.

FAA Regional System Plan Update

Major Issues to be Considered

- **Regional Jets**. Impacts of increase in RJs on services and routes offered at regional airports and the system as a whole.
  Potential for RJs to expand the demand for travel between the New England Region and short/medium range markets
- **Low Cost Carriers**. Impact on the system (i.e. demand stimulation, catchment area expansion, other infrastructure improvements)
- **Other Transportation Modes**. What can be done to use other transportation modes more effectively as complements to the air service system?
- **Ground Access**. Opportunities to improve airport access and passenger convenience that would encourage use of the regional airports?
- Where can **charter**, **air cargo** and **corporate GA** be best served and how can it be accomplished?
- **Service Improvements** at the outlying markets

FAA Regional System Plan Update

Study Structure/Content

Two-Phase Process:

- **Phase I** of the study will address *regional aviation forecasting* and studies to facilitate a possible *reshaping of the market.*
- **Phase II** will consider *Public Policy and Action Recommendations*

FAA Regional System Plan Update

Phase I Tasks

Task 1 –Regional Aviation Forecasting

- Review of existing and planned aviation forecasts
- Forecasts of passenger/charter demand at the city and town level within 100-mile radius of Boston and at county level for rest of region.
- Forecasts of regional cargo demand.
- Detailed forecasts of passenger demand by city pairs for all primary airports in the region sufficient to account for 75% of enplanements. (*may include onsite passenger surveys, ticket-lift analyses or other similar site-specific data collection efforts*).

FAA Regional System Plan Update

Phase I Tasks (continued)

Task 1 –Regional Aviation Forecasting

- Forecast of the region's age-cohort, income distribution and employment by significant industrial sector categories in order to understand major determinants of overall aviation demand within the region.
- Forecasts to be developed for 5 (2005) and 15 (2015) years.
- Forecasts of operations based upon passenger forecasts.

FAA Regional System Plan Update

Phase I Tasks

Task 2 – Shaping the Market

- Identify any new industry trends that might shape the market.
- Define primary catchment areas for the regional airports and identify shifts since the 1995 study. Explain reasons for any identified market area shifts.
- Conduct an inventory of existing and planned passenger, cargo, charter facilities and associated infrastructure that impact services at primary airports within the region.

FAA Regional System Plan Update

Phase I Tasks (continued)

Task 2 – Shaping the Market

- Identify ground access improvements that could enhance passenger and cargo demand at the regional airports.
- Identify range of services and costs of alternative transportation modes, including video-conferencing that have a potential to redistribute regional demand for aviation services. (*DOT Inter-modal group will furnish some of this*).

FAA Regional System Plan Update

Anticipated Phase I Products

- New regional passenger and cargo forecasts
- Updated passenger and cargo fleet forecasts
- Updated catchment areas
- Identification of new service market opportunities
- An understanding of facility needs to accommodate anticipated growth
- A work scope for Phase II
- Development of a public involvement program for Phase I and Phase II

FAA Regional System Plan Update

Phase II Public Policy and Action Recommendations

- Develop an implementation plan/program identifying major actions required to support a regional strategy to enhance air passenger service.
- Develop ongoing planning and evaluation capability to guide evolution of regional strategy as conditions develop beyond original assumptions.
- Evaluate major public policies, alternate airline strategies, federal aviation policies and regulations that could guide regional system planning.
- Identify federal aviation policies and regulations that could be a restriction to cooperative regional intermodal system planning.

FAA Regional System Plan Update

Public Consultation

- Public and agency consultation for input on the work scope and products
- Briefings on topics of high interest
- Consultation with congressional, business, environmental and community groups
- FAA will also coordinate this project within the context of ONEDOT
- Specific timeframes for public involvement have not been fully developed

FAA Regional System Plan Update

Preliminary Schedule

Scoping Activities

Issue Request for Qualifications (RFQ)	February, 2001
Pre-Bid Briefing Meeting	March, 2001
Consultant Selection	March, 2001
Develop Detailed Work Program	April, 2001
System Planning Grant	April, 2001

Phase 1	Begin April 2001
Task 1 Report	August 2001
Task 2 Report	December 2001
Task 3 Phase II Work Program	January 2002

Phase 2	
Phase 2 Grant	January 2002
Phase 2 Report	September 2002

Measures of Delay

The official FAA delays database is the Air Traffic Operations Network (OPSNET), in which FAA personnel record only the number of flights that are delayed 15 or more minutes at a particular facility. The new FAA Consolidated Operations and Delay Analysis System (CODAS) uses existing data sources to produce estimates of flight delays by phase of flight but not by cause. In addition, the U.S. Department of Transportation (DOT) publishes the Air Travel Consumer Report (ATCR) that reflects on-time performance relative to published flight schedules. Each of these delay reporting systems was designed for a specific and different purpose, is based on different data sources or methodologies, and reports flight delays differently. As a result, these measures of delay are not directly comparable and none provides a comprehensive measure of the flight delays at an airport and their causes. However, these measures are useful for identifying which airports in the national aviation system are most affected by delay.

■ FAA Air Traffic Operations Network (OPSNET)

OPSNET is the official FAA delay reporting system for air traffic management purposes.[1] It is used by the FAA on a daily basis to identify where and when delays occurred in the national aviation system, the source of the delays, and their duration.

OPSNET has two major limitations that make it an inappropriate measure of the total delay incurred at Logan in a given year. First, the OPSNET system understates the total amount of delays in the national aviation system. Delays less than 15 minutes are not recorded by OPSNET, nor does it record aircraft on VFR flight plans or airborne delays other than for holding patterns (i.e., speed reductions are not counted). Additionally, total delays are understated because flight delays are recorded separately by each facility. Specifically, FAA personnel in each en route sector and major terminal area manually record the total number of IFR aircraft that suffered more than 15 minutes of delay under their control. Because the 15-minute threshold applies separately to each facility that controls a flight, total delays are understated. For example, a flight from Washington, DC to Boston that may have suffered three 10-minute delays at three different locations (e.g., taxiing out at Washington, in the New York en route sector, and in the Boston terminal area) will not be recorded in the OPSNET data, despite having incurred a cumulative 30 minutes of delay.[2] Finally, OPSNET does not include cancelled flights.

▼

1 OPSNET was formerly known as the Air Traffic Operations Management System (ATOMS).
2 Airside modeling only counts delays attributable to congestion at Logan Airport.

Second, the OPSNET data records the number of delayed flights rather than the extent of the delay incurred. All delayed flights that meet the 15-minute threshold are treated equally, i.e., a flight which was delayed 15 minutes during arrival and one which experienced a 3-hour departure delay are each recorded as a single delay in the OPSNET data. Thus, OPSNET cannot be used to determine the hours of delay incurred at Logan each year.

Because of these limitations, OPSNET is most useful as a comparative indicator of national aviation system performance rather than as an absolute measure of delay at a single airport.

■ DOT Air Travel Consumer Report (ATCR)

The Department of Transportation's Office of Aviation Enforcement and Proceedings issues the ATCR to provide consumers with information about the on-time performance of airline flights. It is based on Airline Service Quality Performance (ASQP) operational data filed by major air carriers and on scheduled times published in the Official Airline Guide (OAG).

The ATCR data is of limited value for measuring total delays at Logan because it is an incomplete database that may seriously underestimate true delays and it attributes delays to airports that may not be responsible for the delay. A serious source of understatement is due to the fact that the ATCR only reports domestic delayed flights for the ten largest US airlines.[3] This means that no information on international or regional flights is contained in ATCR, an important gap for Logan where commuter and international flights are 53 percent of total operations.[4] Cancelled flights or those delayed by aircraft mechanical problems are also not reported in this database.

While the ATCR, like OPSNET, uses a 15-minute threshold to define a "delayed" flight, the ATCR calculates delays for individual flights by comparing actual and scheduled departure and arrival times. This method of counting delays and the fact that airlines normally make an allowance in their published schedules for expected ATC and airport delays is another source of understatement. For instance, the scheduled arrival and departure times for a flight may already include a 10-minute allowance for delay. Thus, if the flight arrives 25 minutes after its scheduled arrival, the flight actually incurred 35 minutes of delay, not 25. In this respect the "on-time arrival statistics" published in

▼

3 Based on airlines with one percent or more of total domestic scheduled passenger revenue in the US. These include: Alaska Airlines, America West Airlines, American Airlines, Continental Airlines, Delta Air Lines, Northwest Airlines, Southwest Airlines, Trans World Airlines, United Airlines, US Airlines.

4 Based on Massport statistics for the 12 months ended June 30, 1999.

the Air Travel Consumer Report each month underestimate the true incidence of arrival delays of 15 minutes or more.

The ATCR records delays as small as one minute, and can aggregate delays by individual flight, by carrier and by airport. For an individual flight the ATCR includes delays incurred on all upstream legs. For example, a flight from St. Louis via Pittsburgh to Boston, which is scheduled to arrive at Logan at 10:15, but actually arrives at 10:40, is reported to have a delay of 25 minutes at Boston. It does not matter where in the system the delay occurred. The flight is counted as a delayed flight if the delay occurred at Logan, en route, at Pittsburgh, or even if the flight was 25 minutes late departing St. Louis. While the ATCR "debits" Logan for arrival delays that may be caused by late departures from the point of origin, it would be inappropriate from an airport planning perspective to count these as Logan related delays.

■ FAA Consolidated Operations and Delay Analysis System (CODAS)

The Consolidated Operations and Delay Analysis System was created by the FAA Office of Aviation Policy and Plans (APO) to provide more consistent estimates of aircraft delay by combining data from several existing sources. CODAS, which was implemented in January 1997, calculates delays by phase of flight: gate-delay, taxi-out delay, airborne delay and taxi-in delay.

CODAS integrates data from two primary sources: the FAA's Enhanced Traffic Management System (ETMS) and the DOT's Airline Service Quality Performance (ASQP) System. Back up data come from the Official Airline Guide (OAG), the carriers' Computerized Reservation Systems (CRS) and the Air Transport Association (ATA). In addition, APO independently estimates unimpeded taxi times. Each of these data sources was independently created for another purpose and each has its own strengths and limitations.

While CODAS represents a significant improvement in the tabulation of flight delays, it is not without limitations as a tool for airport planners. For one thing, it measures delay where it occurs, not where the delay is caused, e.g., gate-hold delays at Los Angeles due to congestion at Logan are recorded as delays at Los Angeles. CODAS also understates the actual delays in several ways. First, although it only tracks IFR flights, many of these are not included. For example, the two available years of CODAS reports contain only 75 percent of the Logan operations that are in the OPSNET database. Finally, as with all the measurement systems, flight cancellations are not included.

■ Overview of Delay Measures

Each of the FAA and U.S. DOT delay databases measures a different aspect of delay. OPSNET counts only the number of flights that suffer a delay of more than fifteen minutes at a single element of the ATC system (sector or airport). By concentrating on single elements separately, without regard to overall flight performance, OPSNET underestimates by a wide margin the number of aircraft truly delayed by more than 15 minutes. ATCR measures delay in terms of deviation from the scheduled arrival time of the aircraft. Insofar as airline schedules already include allowances for expected delays, ATCR statistics may seriously underestimate true delays. ATCR is not concerned with the causes of delay and may "debit" an airport for delays that are due to "upstream" congestion or to other events that have nothing to do with that airport. CODAS is the most useful of the available databases since it includes the ASQP measurements, actual FAA operations data, airline schedules and other information. However, it does not include any information on delay causes, it misses many flights, and it generally under-reports airport delays. Table 1provides a summary of the features and limitations of each of the existing sources of flight delays.

Table 1
Comparison of Flight Delay Measurement Sources

Source	Features	Limitations
OPSNET (FAA)	Measures number of delayed flights Official FAA delays source Delays computed for each FAA facility	Does not count delays less than 15 minutes Does not count cumulative delay across flight sectors Excludes VFR flights Excludes taxi-in delays Excludes linear airborne delays Omits flight cancellations
CODAS (FAA)	Minutes of delay by phase of flight Delays for all major US airports Combines best of available data on schedules and actual times	Excludes VFR flights Not all flights recorded, esp. commuters and busy times No causal information Runway configurations ignored Estimates of unimpeded taxi times Flight cancellations omitted
ATCR (DOT)	Monthly consumer reports Actual aircraft arrival/departure times Delays by airport, airline and individual flight	Only 10 largest US airlines included Excludes regional and international flights No causal information No information on flight phase "Upstream" delays included

■ Simulation Modeling for Airport Delay Estimates

Since none of the delay measurement systems presents a comprehensive picture of actual delays at an airport, estimates of the total airfield delay have been developed using computer simulation models. DELAYSIM, the model used for the Logan Airside Improvements Planning Project, estimates that Logan experienced 120,000 annual hours of runway delay in 1998. (See Chapter 4 for a more detailed discussion of delay models.) This is more than six times the FAA's 20,000 annual hour threshold for identifying delay problem airports. However, even these annualized delay hours obscure the true impact of delay at Logan. During periods of excessive northwest winds, delays can exceed three hours per operation. (See Northwest/Southeast Winds Case Study in Appendix I in the Draft EIS/EIR).

The FAA uses airfield simulation models, not historic data, for evaluating major airport improvements such as the Logan Airfield Improvements.[5] FAA orders require the use of simulation when calculating benefits of major investments, like runways, that involve the use of discretionary funds. Simulation has the essential ability of projecting future performance in response to proposed changes in facilities. It can track and aggregate smaller levels of delays as well as the aggregate delay across all phases of operation. Simulations do not normally cancel flights during periods of extreme delay even though airlines are often forced to cancel flights in these conditions. By estimating the delay that would have occurred, the simulation accounts for the cost of such cancellations.

Simulation models are not validated by comparing them to historic delay data since the FAA does not have a system to comprehensively record the appropriate delays. Instead, simulations are validated by comparison with airfield performance characteristics such as hourly capacity, runway occupancy times, runway exit distributions, taxiway routings, etc. In addition, air traffic control specialists are consulted regarding key assumptions in the model.

Review of Forecast Regional Jet Utilization
Proposed Runway 32 at Logan International Airport

Prepared for the FAA by Jim Muldoon

Proposed Runway 14-32 at Logan is intended to provide an additional landing runway (r/w 32) during northwest wind conditions for smaller aircraft, principally regional turboprops, and to reduce airfield delays during those conditions. Recently updated forecasts indicate that the volume of regional turboprops will continue to reduce and that the volume of regional jet (RJ) operations will significantly increase. The question then is - "Will the 5000 ft length proposed for runway 14-32 be adequate for the RJ's included in the current Logan forecast?"

A paper prepared by SH&E tabulates the minimum landing distance for the three regional jets, which are forecast to operate at Logan in significant numbers:

Canadair CRJ-200	4,848 ft.
Embraer 145*	4,494 ft.
Fairchild 328 Jet	3,887 ft.

* For the purpose of this analysis I have added the Embraer 135 with a minimum landing distance of 4,200 ft.

A review of manufacturers published performance information, as well as the appropriate sections of the FAA Aircraft Certification and Air Carrier Operating Regulations, confirms the accuracy of these lengths for a maximum landing weight, on a "standard day", with a dry runway and zero wind. In actual operations these length requirements would be reduced or increased based upon prevailing operational conditions. Specifically, the length required would be reduced at landing weights less than maximum, with the likely presence of a headwind component and at temperatures less than 57 degrees. On the other hand, the lengths would increase with a wet runway (by 15%) and at higher ambient temperatures.

Given the expected range of operating conditions it is clear that the Fairchild RJ's would be able to plan on landing on a 5000 ft runway at Logan in accordance with the applicable regulations whenever the runway is in use, and that the Embraer 135 would encounter operating conditions that would prevent a legal landing on the runway very rarely. A similar range of operating conditions would, however, prevent the Canadair RJ and the Embraer 145 from legally dispatching against a 5000 ft. runway at Logan some significant portion of the time.

If the question were simply - Can these RJs legally conduct landings on the proposed runway? - a straightforward weather/performance analysis would probably establish a usability approaching 100% for both the Embraer 135 and Fairchild RJ's and a somewhat lower factor for the Embraer 145 and a lower still factor for the Canadair RJ.

In light of RJ operator requests for runway lengths greater than 5000 ft. at other airports and instances of non-use or a low volume of use of similar runways at other airports the more difficult question is - Will these RJ's operators accept a 5000 ft landing runway at Logan regardless of legal adequacy? Based upon the locations I was able to investigate, I believe that runway use estimates arrived at using "by-the-book" or "legal" requirements should be reduced somewhat.

Operator requests and supporting planning studies at airports, not presently receiving scheduled jet service, have indicated a need for runway lengths of up to 7,000 ft. to support RJ service. Typical of these locations are Sallisbury and Hagerstown Md., where recent analyses established a need for 6,000 to 7,000 ft. for the Embraer (ERJ) and Canadair (CRJ) respectively. These lengths are, however, predicated on takeoff requirements for a reasonable stage length and load factor. The landing lengths noted in the studies, although not critical to supporting the need for a specific runway extention, are, when adjusted back to sea level, essentially the same as those noted above.

Operator requests that at least a 7,000 ft. landing runway be provided during the construction staging at Cleveland Hopkins International Airport have also raised questions as to the suitability of a 5000 ft. landing runway for RJ's at Logan. Investigation indicated that the justification for a 7,000 ft. length at CLE was based on accommodating about 90% of all jet landings, which included virtually all narrow bodied air carrier jet aircraft. Again the landing distance requirements tabulated for the RJ's in the CLE fleet, when adjusted back to sea level were essentially the same as those noted above.

The reported lack of activity on the relatively new 5000 ft. runway at Philadelphia International also raises questions on the acceptability 5000 ft. at Logan. Investigation indicates that there are a number of factors which continue to limit the use of the runway for all commuters, not just the CRJ's operated at PHL by US Airways. Relatively long taxi distances, a land-and-hold short problem and the lack of Precision Runway Monitoring (PRM) equipment are all cited as factors that negatively affect the use of the runway. The hope, on the part of the consultants who planned and managed the construction of the runway, is that with the completion of the new commuter terminal and the commissioning of a PRM system late this spring the use of the runway will increase dramatically.

At Baltimore Washington International a 5000 ft commuter runway has been available since the late 1980's. Although US Airways operates CRJ's at BWI, the ongoing capacity study at the airport indicates no significant landing activity on the runway by RJ's. Conversations with ATC and airport operations people at BWI did not identify any mitigating factors affecting the use of the runway such as those noted at PHL, in fact non-jet commuter aircraft heavily use the runway when conditions permit. It appears clear that the CRJ operators are simply rejecting the runway because the length is, in their view, marginal.

Based on the specific experience at BWI, and the very small margin between the minimum calculated dry runway requirement and the length proposed at Logan, I do not believe that it is reasonable to anticipate any CRJ landings on runway 32 at Logan.

Recognizing that the wet runway requirements for both the Embraer 135 and 145 are just under (4830 ft.) and just over (5168 ft.) the proposed length, I do not believe that is reasonable to anticipate any ERJ landings on the runway in wet runway conditions.

On the other hand I believe that the margins for both ERJ's in dry conditions and for the Fairchild 328 both wet and dry are sufficient when combined with the operational advantages offered by the use of runway 32 to anticipate full use of the runway by those aircraft when conditions permit.

In summary, based upon the investigation outlined above, the following recommendations are offered for estimating RJ landings on runway 32 as an input for additional delay reduction and noise impact analyses:

- assume no landings by the Canadair CRJ-200
- analyze historical weather data to establish the percentage of time that landings would be conducted on runway 32 in "wet runway" conditions,
- allocate landings by both the Embraer 135 and 145 to other landing runways during those periods when runway 32 is a landing runway and wet runway conditions prevail.
- assume the balance of the RJ fleet will be capable and willing to land on runway 32.

Appendix D
Northwest Wind Runway Use Restriction

➤ D.1 Case Study

D

Evaluation of Proposed Northwest Wind Restriction on Unidirectional Runway 14/32

One of the issues raised in the FAA Panel Process was the possibility of restricting the availability and use of Runway 32 to Northwest wind conditions only. This proposal was designed to limit the increase in the number and proportion of jet departures on Runway 27 that was predicted to occur with construction of the new runway. Runway 27 is the principal departure runway used in combination with arrivals on Runways 33 and 32 in the new three-runway configuration that would become available with construction of unidirectional Runway 14/32. With the proposed new runway, Logan would have three-runway configurations available in three distinct operating directions: to the north using Runways 4L/4R and 9, to the south using Runways 22L/22R and 27, and to the northwest using Runways 33/32 and 27.[1]

Currently, when wind conditions require air traffic control to route aircraft on a northwesterly heading, available airfield capacity declines sharply from Logan's normal three-runway capacity down to the capacity of two, and sometimes just one runway. As described throughout this report, the construction of Runway 14/32 would prevent this substantial decline in airfield capacity, and the resulting aircraft delay that now occurs under these conditions.

The increased usage of Runway 27 projected in the airfield simulation modeling reflects the availability of this new three-runway configuration in the northwest direction. This configuration would not only allow controllers to nearly eliminate northwest wind delays at Logan, but would also enable air traffic control to more evenly distribute aircraft overflights across three different operating directions during periods of high demand. As discussed in Chapter 4, this flexibility leads to a significant improvement in the ability of air traffic control to achieve the Preferential Runway Assignment System (PRAS) goals and provides relief to residents of communities impacted by use of the existing north and south runway configurations.

---

[1] *Construction of the proposed new runway would also create a fourth three-runway configuration—Runways 15/14/ and 9—in a southeast alignment. However, this configuration would have limited arrival capacity.*

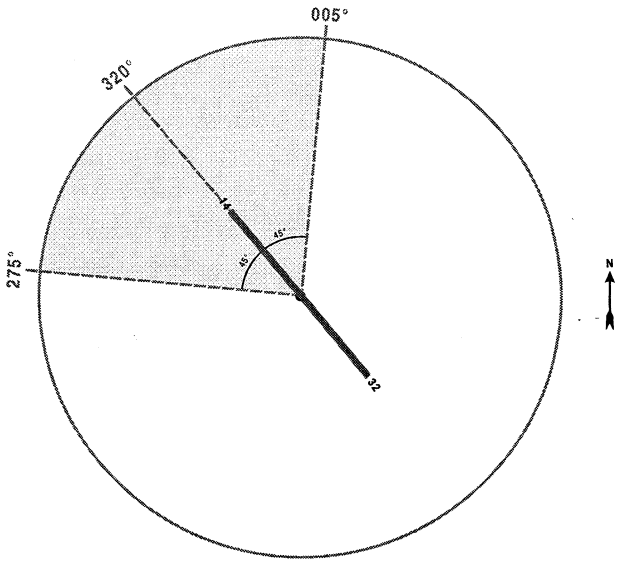
Utilization of the new three-runway configuration (33/32 and 27) to improve PRAS achievement results in a predicted increase in the percent of jets using Runway 27 for departure, above the level that would occur if the configuration was used only to reduce delays resulting from northwest winds. Numerous public comments received on the Draft EIS/EIR objected to a "tripling of overflights" off Runway 27 that was forecast to occur with the construction of Runway 14/32.

For this Supplemental Draft EIS, analysis was performed to determine how restricting the use of Runway 32 to northwest wind conditions would impact the delay reduction benefits produced by the runway as well as the associated utilization of Runway 27 for jet departures. Other changes in runway utilization were identified, as were the implications of the restriction on PRAS achievement and noise exposure patterns. In framing the analysis, rules were developed to identify the wind direction and wind speed under which the Runway 32 would be available for use. These parameters are described below.

Wind Direction

In the wind restriction scenario, Runway 32 was made available for arriving aircraft only when the wind direction was within the 90-degree quadrant between 275° and 005° (i.e., 45 degrees on either side of the 320° runway heading). The wind direction criterion is displayed below in Figure 1. When the wind direction was not within the defined quadrant, Runway 32 was not available for use.

Figure 1.
Quadrant Restriction



Wind Speed

Alternative wind speed criteria of 5, 10, 15, 20, and 25 knots were used to evaluate the proposed restriction on Runway 32. Under the 5 knot scenario, Runway 32 was available for arrivals when wind direction was between 275° and 005°, and wind speed with gusts was 5 knots or greater. As the wind speed threshold was progressively increased from 5 knots to 25 knots, the percent of time in which the runway was available for use declines. For context, FAA Order 7110.65 Air Traffic Control recommends use of the runway most nearly aligned with the wind, when wind speed is 5 knots or more, unless use of another runway would be operationally advantageous or is requested by the pilot.

Weather

Hour-by-hour Boston weather data for the three year period between 1997 and 1999, as reported by the FAA in the CODAS weather database, was used in performing the analysis of the potential wind restriction. This is the same weather database that was used in evaluating all of the proposed airfield improvements for the 2015 RJ Fleet scenario.

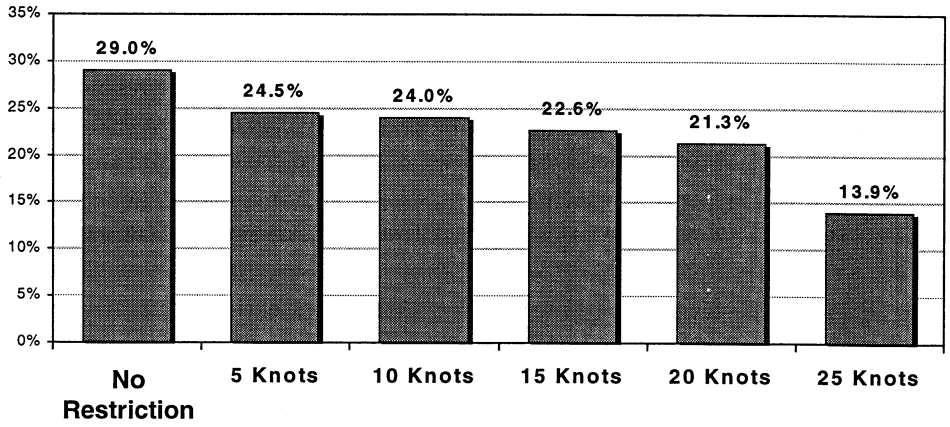
Fleet Scenario

The proposed wind restriction was evaluated based on the 2015 37.5 million passenger RJ Fleet scenario. This fleet represents the third alternative fleet scenario designed to accommodate 37.5 million annual passengers, along with the 37.5 million High Fleet and the 37.5 million Low Fleet. The 2015 RJ fleet has annual operations of approximately 584,000—between the 37.5 High and Low Fleet scenarios—and is characterized by a substantially higher volume of regional jet aircraft and far fewer non-jet aircraft than is present in either of the previously evaluated 37.5 million fleets.

Delay Reduction Impacts

Without any restriction on the use of Runway 14/32, the Preferred Alternative 1A produced a 29 percent reduction in forecast annual delay hours at Logan. Figure 2, below shows the percent reduction in annual Logan delays that could be achieved with various restrictions on the use of the proposed runway.

Figure 2.
Delay Reduction Benefits of Various Wind Restrictions
Percent Delay Reduction: Preferred Alternative vs. No Action, 2015 RJ Fleet



With a 5-knot northwest wind restriction, the delay benefits of Runway 14/32 are somewhat reduced, from 29 percent in the unrestricted scenario down to 25 percent at 5 knots or greater. With a 10-knot northwest wind restriction, Runway 14/32 reduces annual delays by 24 percent. Allowing use of Runway 32 only in northwest winds of 25 knots or greater, the delay reduction benefits are cut by more than half, from 29 percent (unrestricted) down to just 14 percent.

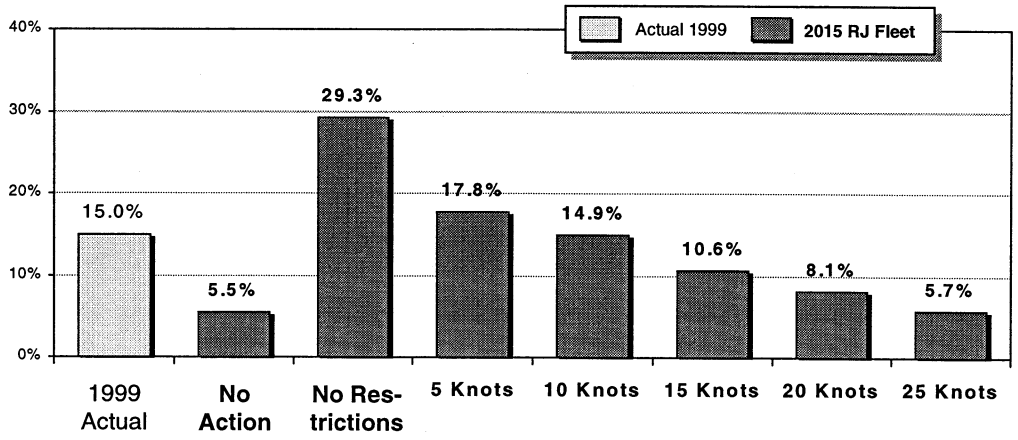
Clearly, the greatest delay reduction benefits are associated with unrestricted availability of the proposed runway. As the circumstances under which air traffic controllers are permitted to use the runway become increasingly limited, the delay reduction benefits associated with the runway are reduced.

Changes in Runway Utilization Patterns

Limiting the use of Runway 32 to northwest wind conditions has impacts on the predicted patterns of runway utilization at Logan. Figure 3 shows that, as intended, the restriction does limit the increase in jet departures using Runway 27. With an unrestricted runway, the use of Runway 27 is projected to increase from 6 percent of jet departures under the No Action scenario up to 29 percent with the Preferred Alternative. With a 5-knot northwest wind restriction, the use of Runway 27 is projected to increase to only 18 percent of jet departures, compared to the 30 percent use in the

unrestricted case. With a 10-knot restriction, the use of Runway 27 is only 15 percent. With a 25 knot restriction, Runway 27 use matches the No Action value of 6 percent. For comparison, in 1999 Runway 27 was used by 15 percent of Logan's jet departures.

Figure 3.
Runway 27 Jet Departures as a Percent of Total



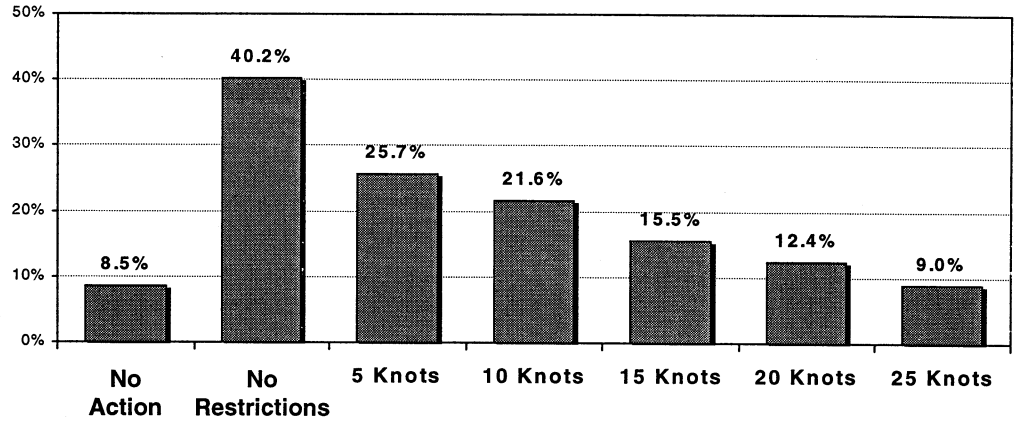
However, restricting the use of Runway 32 has three undesirable consequences:

- The restriction would limit the ability of FAA controllers to increase use of over-the-water flight paths.
- The restriction would increase activity on the north and south runways relative to the unrestricted Preferred Alternative. The north and south runways are already the most heavily utilized runways at Logan.
- The restriction would hamper the ability of air traffic controllers to achieve PRAS goals, including both the annual runway use targets and the short-term goals to limit dwell and persistence.

Over-the-Water Arrivals

The availability of Runway 14/32 and the new three-runway configuration (33/32/27) allows controllers to maximize the use of over-the-water flight paths at Logan. In the 2015 RJ Fleet for example, jet arrivals on Runways 33 and 32 would increase from approximately 22,000 per year (or 9 percent of jet arrivals) under the No Action scenario up to more than 100,000 annual arrivals (or 40 percent of total) with an unrestricted runway.

Figure 4.
Over-Water Jet Arrivals as a Percent of Total

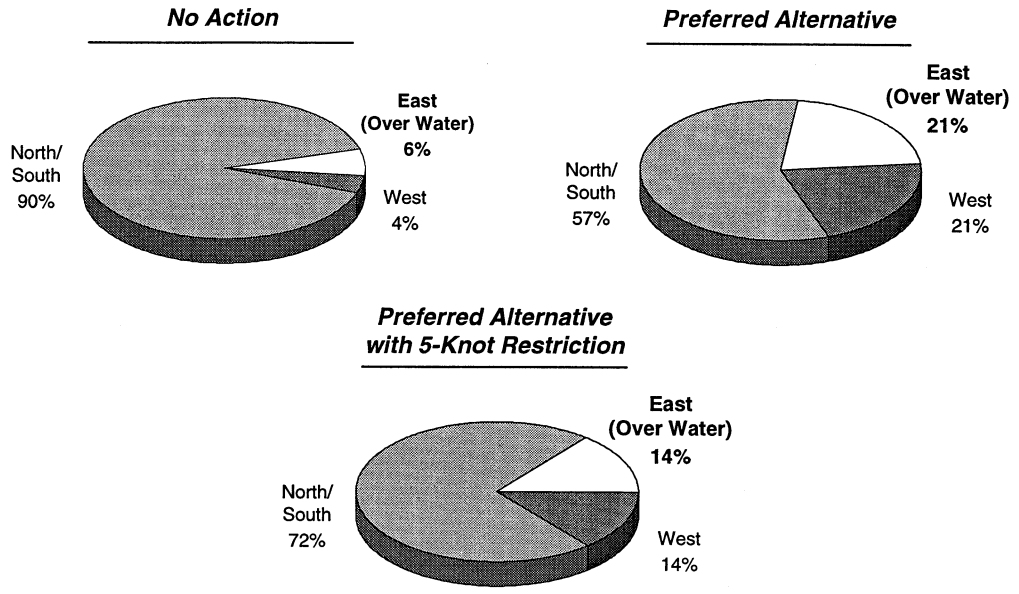


As shown in Figure 4, applying a northwest wind restriction to the use of Runway 32 limits the ability to route more inbound flights over the water. With a 5-knot northwest wind restriction on Runway 32, over-the-water jet arrivals would decline by more than one third to approximately 65,000 annual flights, or 26 percent of total. As the northwest wind restriction is tightened to require higher wind speeds, there is a further loss in the ability to route inbound flights on an over-water approach. With a 25-knot wind restriction on the use of Runway 32, only 23,000 annual jets would arrive on over-water flight paths to Runways 33 or 32, barely above the number of over-water jet arrivals estimated without the new runway under the No Action scenario.

Increased Use of North/South Configurations

While a northwest wind restriction on the use of Runway 32 would lower the utilization of Runways 33, 32 and 27, the restriction would produce a corresponding increase in usage of the north and south runways at Logan. A major advantage of the (unrestricted) runway was that it could provide relief to communities impacted by jet activity on the north/south runway configurations (4R/L, 22R/L, 27 arrivals, 9 departures) that receive the majority of Logan's jet flights. As shown in Figure 5, construction of Runway 14/32 and its unrestricted availability could reduce utilization of these north/south configurations from 90 percent (2015 RJ Fleet) to 57 percent.

Figure 5.
Jet Overflights by Direction – *2015 RJ Fleet*



If use of Runway 32 were restricted to northwest wind conditions, much of this beneficial reduction in north/south runway utilization would be sacrificed. At a 5-knot restriction, use of the north/south runways would reach 72 percent, while at a 15-knot restriction, north/south runway utilization is estimated at 83 percent.

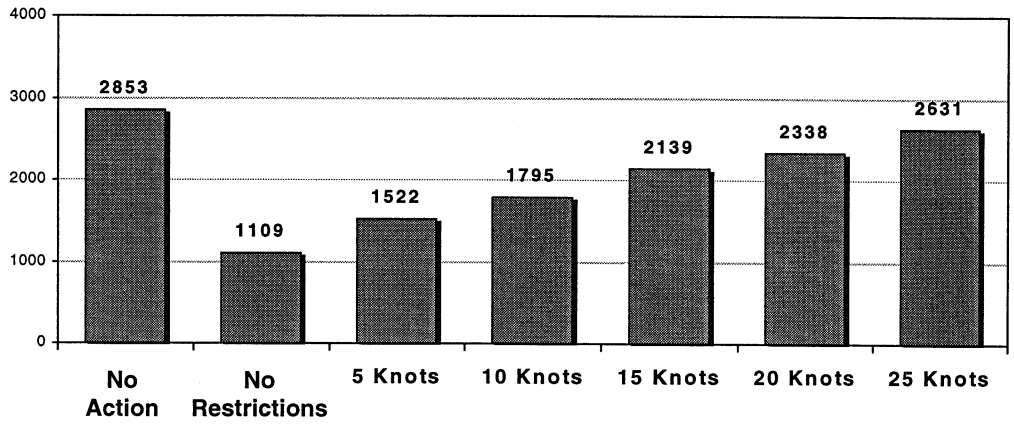
PRAS Performance

By providing a third three-runway configuration at Logan, the new runway would enable controllers to more evenly distribute flight activity across different runways, and thereby enable a significant improvement in the ability to achieve PRAS goals. The PRAS Performance Index (PPI), described previously in Section 4.3.4.7 of this Supplemental Draft, measures the extent to which air traffic controllers are able to achieve the annual runway utilization goals. The more closely actual runway utilization mirrors the PRAS goals, the lower the resulting PPI value.

Figure 6 compares the PRAS Performance Index values for the 2015 RJ Fleet scenario under the No Action scenario, with an unrestricted Runway 14/32, and with various levels of northwest wind restrictions. As illustrated in the graphic, the unrestricted availability of the proposed runway would permit a 61 percent improvement in

achievement of the annual PRAS runway use goals—from an index value of 2853 (No Action) down to 1109 (Preferred Alternative).

Figure 6.
PRAS Performance Index – *2015 RJ Fleet Scenario*



Placing a northwest wind restriction on Runway 32 limits the potential improvement in PRAS performance. At a 5-knot wind restriction, the PRAS index climbs to 1522, sacrificing 23 percent of the improvement permitted with an unrestricted runway. As the wind speed restriction is progressively increased, the potential gain in PRAS performance is further diluted.

In addition to the long-term runway use goals, PRAS also has short-term goals for dwell and persistence, described in Section 4.3.2.2 of this Supplemental Draft. As with the long-term goals, the northwest wind restriction limits the ability of air traffic controllers to improve short-term PRAS performance. Annual dwell exceedance improves from 2,107 hours under the No Action scenario to 1,407 hours with the Preferred Alternative. A 5-knot restriction, allows dwell exceedance to climb back to 1,851 hours, and a 15-knot restriction increases dwell to 1,972 hours. The northwest wind restrictions have a similar impact on persistence exceedance.

Noise Impacted Population

Because restricting the use of Runway 32 would change runway utilization at Logan, the restriction would also impact the airport's noise contour and the resulting noise exposure patterns. To illustrate these changes, noise impacts with a 5-knot northwest wind restriction were compared to projected noise exposure patterns occurring with an unrestricted runway. As shown in Figure 7, restricting the use of Runway 32 would cause more people to experience noise exposure levels of greater than 70 DNL. This increase is concentrated in the communities of Revere and Winthrop, and is the result of greater use of the north/south runway configurations that occurs when use of 33/32/27 is limited by the 5-knot restriction.

Figure 7.
Population Impacts of a 5-Knot Northwest Wind Restriction – *2015 RJ Fleet*

		Preferred Alt.		
Area Impacted	**No Action**	**Unrestricted**	**5-Knot Restriction**	**Change**
DNL 75 and above	222	58	58	-
DNL 70 and above	3,700	2,267	3,144	877
DNL 65 and above	11,493	11,857	11,671	(186)
DNL 60 and above	36,857	50,048	45,582	(4,466)

At the same time, the population experiencing noise exposure above 65 DNL declines by two percent with the northwest wind restriction. This decline takes place because of the lowered utilization of Runway 33 for departures which reduces the number of people in East Boston (Eagle Hill) exposed to noise levels of 65 DNL or above.

Complete population counts by community and noise exposure level are shown in Figure 8.

Findings

In summary, the proposed northwest wind restriction on Runway 32 would have the following consequences:

1. A northwest wind restriction would sacrifice a portion of the delay reduction benefits that could be realized through unrestricted usage of the runway. Even at the least severe 5 knot wind restriction, Logan would experience 17,000 more hours of annual aircraft delay under the 2015 RJ Fleet scenario than it would with an unrestricted runway. As the wind speed criteria is increased, further limiting the circumstances in which the runway could be used, the delay benefits of the runway are progressively eroded.

2. The proposed restriction does limit the increase in jet departures off Runway 27 that results from its use in combination with Runways 33 and 32. With a 5-knot northwest wind restriction, usage of Runway 27 declines from 29 percent to 18 percent of total Logan jet departures. The utilization of Runway 27 for departures drops further as the wind speed criteria on Runway 32 is increased.

3. However, the decreased usage of Runway 27 corresponds with other, less desirable changes in runway utilization at Logan. Restrictions on the use of Runway 32 would limit the number of aircraft using over-the-water routings to Runways 32 and 33. The proposed restriction also sacrifices potential relief to residents of communities impacted by the prevailing north/south runway configurations at Logan.

4. Restricting the use of Runway 32 would reduce the ability of air traffic controllers to achieve the PRAS goals, including the annual runway use goals and the short-term goals designed to limit dwell and persistence of overflights impacting individual communities.

5. A wind restriction on the use of Runway 32 would increase the number of people exposed to the highest noise levels above 70 DNL (compared to an unrestricted runway). However, the restriction would at the same time lower the population exposed to noise levels greater than 65 DNL. These impacts occur due to changes in runway utilization patterns that result from restricting the use of proposed Runway 14/32.

Mr. Ken Eldred
Ken Eldred Engineering
Meadow Cove
P.O. Box 501
East Boothbay, ME 04544

Dear Ken:

This is in response to your letter dated March 14, requesting approval to modify the Integrated Noise Model (INM) 5.0 aircraft profiles for use in the Massport Logan Airside Improvements Planning Project Environmental Impact Statement (EIS) and Report (EIR). These modifications will improve the agreement between H-;M results and measured noise data obtained from the Boston Logan International Airport (BOS) permanent noise monitoring system.

You are hereby authorized to modify aircraft takeoff profiles by adjusting thrust values at the start of the takeoff roll point and at the liftoff point to increase the SEL during ground roll by 6 dB. You are also authorized to modify aircraft landing profiles by adjusting thrust values at the 1,000 foot altitude point and at the touchdown point to increase the SEL during the final phase of landing by 4 dB. These changes are warranted given the differences due to excess ground attenuation over water at BOS versus what is modeled in INM over grass covered ground. Additionally, the modifications are warranted because the comparisons were made using the large amount of data obtained from the BOS permanent noise monitoring system.

Please understand that this approval applies only to the modification of takeoff profiles at ground roll and of approach profiles during final phase of landing as part of this BOS EIS and EIR. Any additional projects or non-standard]NM input for BOS will require separate approval. If you have any questions or need additional assistance, please contact Donna Warren by phone at (202) 267-3571, by FAX at (202) 267-5594, or by EMAIL at donna-warffen@mail.hq.faa.gov.

Subject: **Request to Modify Profiles in E'~M 5.0 to Improve Agreement Between INM Calculated and Measured Values of DNL at Boston Logan International Airport for Use in the Massport Logan Airside Improvements Planning Project EIS/EIR**

Dear Mr. Gulding,

This letter contains a request to the FAA to approve adjustments to the Prof pts.dbf data base in the FAA Integrated Noise Model (INM) Version 5.0 to adjust part of the differences between the measured and calculated values of Day-night Sound Level (DNL) at locations that are close to Logan International Airport. The measurements were made by the permanent noise monitoring system at the airport, and the calculations were made by various versions of the Federal Aviation Administration (FAA) -Integrated Noise Model (INM). Differences of 4 to 9 Decibels (0) were observed at several of the noise monitoring stations, with the calculated values lower than the measured values in all but one site.

The adjusted INM calculations are to be used in the noise analysis of the Logan Airside Improvements Planning Project. This project will evaluate the impacts of a series of runway, taxiway and administrative improvements which are directed at reducing current and future congestion and delay conditions at Logan. These analyses will be published in a Federal Draft Environmental Impact Statement (Draft EIS) which will be issued jointly with a Draft Environmental Impact Report (DEIR) prepared pursuant to the Massachusetts Environmental Policy Act.

Since 1981 the noise contours at Logan have been calculated with the INM Version 3.9. In the intervening years the INM database has been upgraded three times from database # 9 to 11 and to INM 5.0. The current database contains data on 103 airplanes, 23 more than in database 9, and include many new models that are needed for the analysis of airport noise in future years. The basic computer program has also been upgraded and the newest version 5.0 became available in mid 1995. Version 5.0 is significantly enhanced in its capabilities over Version 3.9, particularly with respect to

the variety of output data available and its graphics. Because Version 5.0, with its database, is the most appropriate available airport noise model for predicting airport noise in future years, it is proposed to be used in the Airside Improvements Planning Project.

Because of the prior history of differences between calculated and measured values of DNL at close-in locations, an analysis was undertaken of the measured and calculated results for 1993 operations at Logan. The purpose of the analysis was to ascertain the magnitudes and possible causes for the differences, and examining the improvements that could be obtained by adjusting the INM. Table I contains the comparison of 1993 measured DNL values at the sound monitoring stations which are located close to Logan with values calculated by both INM Versions 3.9 and 5.0.. This table shows that both MM versions calculate DNL values that are generally lower than the measured values. The possible reasons for these differences become more evident when the results are grouped by the estimated probable most significant contributor to the DNL value, ie. "airborne takeoffs", "airborne landings", "ground roll during takeoffs" and "all".

The results at these 10 close-in noise monitoring sites show that the INM 3.9 DNL values average 0.2 dB high for "airborne takeoffs", 4.1 dB low for "airborne landings", 7.1 dB low for "ground roll during takeoffs" and 4.6 dB low for "all". The averages for Version 5.0 are similar in magnitude at these locations. The largest difference is associated with noise during the ground-roll segment of takeoff, and the next larger difference is associated with landing noise. The values for "airborne takeoff' are in agreement as would be expected, for this is the condition for which most of the INM validations have been made.

The underprediction of the noise during the ground roll segment of aircraft takeoffs appears to result from the algorithms in the R~M that calculate the noise during ground roll and the excess attenuation experienced by sound propagating over the ground.. The ground roll algorithms provide a reduction in the sound levels behind the aircraft, which appears to overstate the observed reductions at distances greater than 1000 feet. The excess ground attenuation algorithm provides values of attenuation that range from 0 dB at 0 distance up to about 14 dB at distances of 3000 feet or greater. These values of attenuation are in addition to those provided by inverse square loss and air absorption,

Because Logan has water between its runways and most of its closest neighbors, its conditions differ from those of grasscovered ground for which the INM excess ground attenuation was derived. The water does not have the ability to absorb sound as does grass. In addition, the cold temperature of the water probably stabilizes the thermal gradients so that the sound propagating parallel to the ground is not refracted upwards by the daytime sun as it is over ground. Finally, because aircraft generally take off into the wind, the nearest neighbors at Logan are rarely located upwind of an aircraft taking off on the nearest runway. Consequently, the noise that they hear from the ground roll takeoff segment is not often refracted upwards by wind gradients, affecting both the directivity pattern at distance and the excess ground attenuation. For all of these reasons it would be expected that the INM prediction of noise from ground roll is lower than the values experienced by the nearest residents at Logan.

At the two sites identified with "landing" noise the INM computed sound exposure levels for several individual representative aircraft appeared to be lower than data that were obtained for individual flights from the sound monitoring system. This may result from thrust variation during approach and the use of more thrust during the final stage of landing than that contained in the standard profiles in the RW database.

During 1994 we developed an adjustment to R*4M 3.9 to adjust for part of the underprediction of noise from takeoff ground-roll. This adjustment was used in calculating the forecast 1999 DNL 65 dB noise contour for the Home Sound Insulation Program. The adjustment consisted of a change in the algorithm for excess ground attenuation which delayed the full effect of the attenuation until a greater distance from the aircraft. In this analysis adjustments were developed for both takeoff round-roll and arrival profiles to be used with INM 5.0. The proposed takeoff ground-roll adjustment is an addition of 6 decibels to the noise from the airplane during ground-roll. The proposed arrival adjustment is an addition of 4 db to the noise from each type of jet airplane during the last stage of approach. Both adjustments are implemented in the profile points database input to INM 5.0 by increasing the thrust in the region of interest so that the model calculates an appropriately higher value of SEL during that part of the profile. Comparisons of the SEL values at selected locations for a variety of jet aircraft types are presented in Attachment A.

Table 2 contains the data from Table I with the addition of the results calculated from adjustments to the two INM versions. The adjustment to INM 5.0 profiles reduced the average difference between measured and calculated DNL to 2.2 dB, slightly better than resulted from the adjustment to R,TM 3.9. The landing adjustment to INM 5.0 profiles reduced the average difference to 2.3 dB compared to the 4.3 dB for the adjusted R4M 3.9, and the takeoff ground-roll adjustment reduced the average difference to 3.5 dB compared to 3.6 dB for the adjusted RTM 3.9. These adjusted values represent a clear improvement over the unadjusted values in their ability to match the measured values.

These results demonstrate that the noise at close in locations calculated with the adjusted profiles in the INM 5.0 model agrees more closely with the measured values then does the noise calculated with the standard profiles in the MM 5.0 model. Therefore, we request that the adjusted profiles for the INM 5.0 model be approved for use in the for the environmental studies of noise for the Airside Improvements Planning Project at Logan International Airport.

Sincerely,

Kenneth McK. Eldred

Attachment A:

Comparisons of Takeoff and Landing Noise for Typical Jet Aircraft

The changes to the profiles in the INM 5.0 Database involved increasing the thrust at specific profile points in the PROF_PTS.DBF file so that the SEL computed from the appropriate noise table would be calculated at a higher value. This procedure was applied to the 48 INM jet aircraft that are expected to be used in the Boston Logan International Airside Study.

The takeoff profiles were modified to increase the SEL during ground roll by 6 dB at two profile points. They are the start of takeoff roll and the liftoff points, both at zero altitude. An additional point was inserted into the takeoff profile at 100 feet altitude with the standard database value to assure that any changes to the noise would be terminated by 100 foot altitude. The required standard values of thrust, speed and distance from start of roll for the 100 foot altitude point were derived from the database by interpolation between the 0 and 1000 foot datapoints. The approach profiles were modified to increase the SEL during the final phase of landing by 4 dB at two profile points. They are the 1000 foot altitude point and the touchdown point. at zero altitude. The change in thrust at each profile point was calculated by interpolation in the Thrust-SEL database table for each aircraft and stage length using a 1000 foot slant distance.

Table A1 summarizes the changes along a 1000 foot sideline and the centerline for a 727EM1 aircraft. during takeoff and landing. The 727EM1 with Stage Length I has a takeoff roll of 4513 feet and climbs through a 100 foot altitude at 5014 feet from the start of its takeoff roll. Table AIA shows that its noise is 6 dB greater while the aircraft is on the runway (the 0 and 0-5 NM points) and is only 1.4 dB greater at I NM from the start. This 1.4 dB increase over the standard probably results from the addition of the noise from the takeoff roll profile segments. At greater distances, 1. 5 NM from the start of takeoff roll and beyond, the adjustment has no effect. The differences are slightly different along the centerline because the 6 dB increase was calculated for a 1000 foot slant distance and the relationship between SEL and thrust varies with slant distance.

Table A1B gives a similar comparison for landing of the 727EM1 aircraft. The standard profile descends through a 1000 foot altitude at about 3 NM from the landing threshold. The noise for standard and adjusted computations is the same at distances greater than 4 NM . Between 4 and 3 NM from threshold the SEL difference increases to 3.1 dB and averages out 4 dB from 2.5 NM to the threshold at 0 NM. The results along the centerline are essentially similar.

Table A2 gives a comparison of takeoff noise for both the 1000 foot sideline and the centerline for several aircraft types and for Stage Length 1. The results are given for 4 grid points which cover the first 1.5 NM from the start of takeoff roll. The SEL differences along the foot sideline are essentially 6 dB, as planned. Most of the values at 0.5 NM approach 6 dB, except for a few aircraft which have climbed to over 100 feet by the 0.5 NM location. By 1.0 NM from the start of takeoff roll most of the aircraft are above 100 feet and the differences in SEL are approaching zero. At 1.5 NM all of the

differences are essentially zero. The blank entries in the runway centerline data result from the fact that the cumulative contributions of these aircraft to the total noise exposure was less than 3 %.

Table A3 gives a similar comparison for 5 points in the last 2 NM to the landing threshold. The results along the 1000 foot sideline are close to the planned 4 dB. The average difference along the centerline are slightly lower and more variable. This increase in variability probably results from the differences in the slopes of the SEL-Thrust-Distance relationships for the different engine noise characteristics.

TABLE A1A

COMPARISON OF TAKEOFF NOISE FOR STAGE LENGTH 1 727EM1 AIRCRAFT ALONG THE RUNWAY CENTERLINE AND ALONG A 1000 FOOT SIDELINE AT 0.5 NM INTERVALS FROM START OF THE TAKEOF TAKEOFF ROLL CALCULATED WITH BOTH STANDARD AND ADJUSTED INM 5.0 PROFILES

Memorandum from FTA to the FAA Regarding Noise Screening Procedures

MEMO

To: Federal Aviation Administration, New England Region
Attention: ANE-520.4, Terry Flieger, Airspace Branch
From: Flight Transportation Associates, Inc
Date: February 19, 1999
Subject: Application of FAA Notice 7210.360 *Noise Screening Procedure for Certain Air Traffic Actions Above 3,000' AGL* to Proposed Runway 14/32 Operations

---

1. Purpose: This memorandum provides information on potential increases in noise exposure above 3,000' above ground level (AGL) due to future jet traffic on the proposed unidirectional Runway 14/32 at Boston's Logan International Airport. FAA Notice 7210.360 provides a method for the screening of air traffic changes that may result in increased aircraft noise exposure. The notice applies only to airports where 1) there are at least 1,500 large jet airplanes[1] operations per year (either current or projected), 2) modifications represent a permanent or a planned test; 3) changes concern arrival/departure routes or tracks, used by large airplanes, between 3,000 and 7,000 feet AGL (arrivals) or 3,000 and 18,000 feet (departures) AGL.[2]

2. Background: As part of the Logan Airside Improvements Program a new unidirectional Runway 14/32 is proposed. During the EIS process, thorough investigation of potential aircraft noise impacts below 3,000 feet AGL was conducted using the FAA Integrated Noise Model. To further evaluate potential noise impacts for jet operations above 3,000 feet AGL, FAA Notice 7210.360 may be applied. This FAA notice originates from Order 1050.1 D.

a. FAA Order 1050.1 D, *Policies and Procedures for Considering Environmental Impacts,* establishes policy and procedures and assigns responsibility for ensuring agency compliance with the environmental procedures set forth in the Council on Environmental Quality regulation for implementing the procedural provisions of the National Environmental Policy Act. Typically, the establishment of airways, jet routes or revised air traffic control procedures above 3,000 feet AGL are excluded from the requirement for an Environmental Assessment (EA). However, even in cases where changes will result in noise levels well below the standard criteria for a finding of a significant impact, changes may be considered controversial and thus should be further investigated. Order 1050.1 D provides that actions involving jet aircraft which may generate an increase in the average day/night sound level (DNL) of 5 decibels should be the subject of further analysis. Notice 7210.360 provides a means to assist decision makers as to whether changes normally excluded from the EA process should in fact be the subject of further investigation.[3]

---

[1] For purpose of this memo, the term "larger jet" refers only to jet aircraft of 75,000 lbs or greater.

[2] FAA Notice 7210.360, page 2, FAA, 9/14/90

[3] Ibid.

b. Logan Airside Improvements Project (LAIP). The ongoing efforts to improve Logan Airport efficiency and reduce congestion have included a number of recent projects. LAIP focuses on the airside features of Logan including runway and taxiway improvements. A key proposal involves the building of a new unidirectional Runway 14/32 on the southwestern edge of the airfield, near-parallel with Runway 15R/33L. The proposed runway is to be an "over water" operation with departures only in the 14 direction and arrivals only in the 32 direction. Primarily a regional services runway, it will be used most often by turboprop aircraft with jet traffic limited to those capable of operating on the 5,000 ft. runway.

c. Because the application of N7210.360 involves the examination of large jet operations (over 75,000 lbs.) the LAIP 2010 45 Million passenger, high-operations planning scenario (45MH) was selected for the screening analysis. Of all the forecast scenarios used in LAIP, the 45MH fleet contains the largest number of jet operations (all are Stage 3). It is a "worse case" scenario unlikely to actually occur. This projected fleet contains an average of 520 daily large jet arrivals and an equivalent number of departures. Of the arrivals, approximately 3 percent will use Runway 32 while approximately 1 percent will use Runway 14. All remaining large jet operations will use currently existing runways. For purposes of the N7210.360 screening, the "minimum number of average daily large jet operations" is used. This is determined by comparing 5 percent of the total number of Stage 3 operations with the "threshold operations" provided in the notice.

d. New Jet Flight Tracks proposed for Runway 14/32 are shown in Figure 1. As part of LAIP, actual ARTS data was used to develop INM flight tracks for all operating directions at Logan. The INM tracks were assigned aircraft based on INM type. This allowed the segregation of jet tracks/operations from prop tracks/operations necessary for the screening. Only jet tracks are considered or shown in this analysis. The specific number and type of aircraft assigned to each track was based on actual operations and forecasts developed for LAIP.

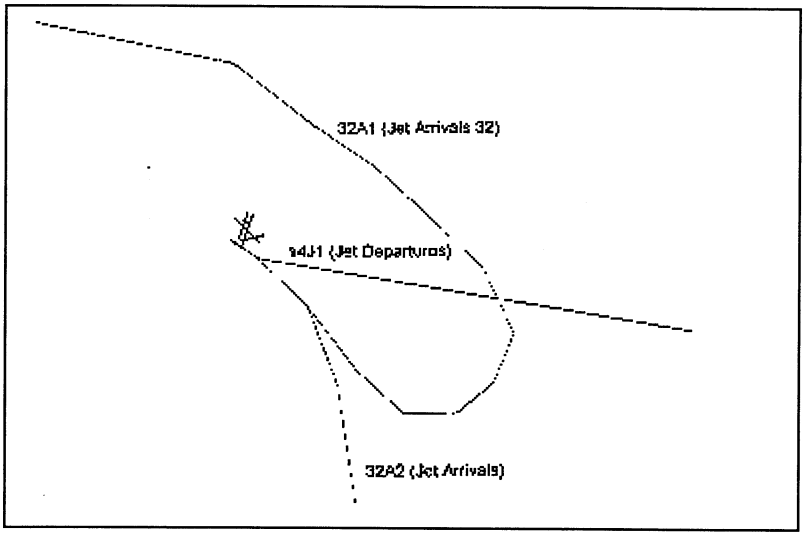

Figure I Runway 14/32 Jet Tracks

New jet tracks for a unidirectional Runway 14/32 were proposed based on safety, efficiency, minimal changes to existing airspace and procedures, and to avoid overflying of residential areas. Track 32A1 coincides with the existing right downwind for 33L until merging with the final for Runway 32 below 3,000 feet. Tracks 32A2 and 14J1 are close enough to existing jet tracks such that no overflights of new areas are considered to occur (see Table 2).

3. Procedure: The application of FAA Notice 7210.360 involves a four-step screening process. Step 1 compares the minimum number of average daily large jet operations[4] on each track with an altitude-based threshold number to determine whether further review is needed. Next, Step 2 considers the proximity of new or changed jet tracks/routes to existing tracks/routes. In Step 3, the change in operations (action versus no action) is translated into approximate decibel levels. For cases where changes or additions result in a 5 dB DNL or greater increase over the no change scenario, Step 4 is applied to determine whether the potential increase is significant based on the land use. If so, further investigation including an EA may be indicated.

4. Step 1, Does the proposed action introduce noise exposure from large jet airplanes which may require further review of the noise impacts as defined in Table 1 of **N7210.360?** According to N7210.360, "The noise screening procedure for air traffic actions applies to *new* or *modified* arrival /departure procedures..." This indicates that only new or altered large jet tracks need be analyzed. The three new jet tracks proposed to serve Runway 14/32 are shown in Figure 1. No changes to existing jet tracks are proposed.

a. In Table 1A, the application of Step 1 to the new jet tracks reveals that five percent of the Stage 3 aircraft that will operate on either Track 14J1 (Runway 14 jet departures) or Tracks A321 and 32A2 (Runway 32 arrivals) for each altitude do not exceed the threshold limits established by N7210.360. As a result, no further analysis is required. Two of the new tracks are completely over water and no significant noise increase will result from their use. Track 32A1 is coincidental with the existing 33L right base pattern until below 3,000 feet where aircraft would transition to the Runway 32 final approach course. It is essentially an addition of traffic to an existing track and no significant increase in aircraft noise exposure will result as shown in Table 1 A. However, because changes in jet operations on other existing tracks may also result in changes in aircraft noise exposure, as in the case of Track 32A1, all jet tracks were analyzed for the LAIP build (Alternative 1A) and no-build (Alternative 4) cases.

b. Due to the number and proximity of tracks used at Logan, all aircraft tracks used by large jets of 75,000 lbs or more were identified and then organized into arrival and departure corridors. A total of 16 arrival and 13 departure corridors were defined (See Figures 2 - 5). Corridors were defined by grouping tracks by direction of flight. Typically, tracks within the same corridor were within 1 to 3 miles of each other. The minimum number of forecasted Stage 3 operations were compared to N7210.360 established threshold levels. This time, however, a comparison of traffic levels within each unique corridor was made rather than on only the two new tracks. The average number of daily Stage 3 operations for each track were estimated using INIVI input files developed for the LAIP EIS/ER. These figures were added for each group of tracks within a common corridor. Since all of these operations are Stage 3 aircraft, the effective number used for the screening procedure was taken as 5 percent of the total average daily operations for each corridor. The screening was completed for both LAIP Alternatives 1A and 4 (See Tables 1 B and 1 C).

c. It was found that in most cases, *existing* flight corridors had *fewer* operations in the build than in the no-build alternative. The only exception to this involved departure operations to the southwest (corridor DSW, primarily from Runway 27), and arrivals from the northwest (corridor ANW, landing on 32/33L). Only the departure operations were found to be above the established threshold levels. This finding led to the need to continue with Step 3 of the notice.

[4] The minimum average number of daily large jet operations is estimated using 5 percent of the daily average number of Stage 3 operations.

Table M Analysis of New Tracks For Runway 14/32

Application of Step 1, Table 1, FAA Notice 7210.360

Alternative 1A (build) with 45MH fleet

Departures

Altitude (AGL)	3,000	4,000	5,000	6,000	7,000	8,000	9,000	10,000	18,000
7210.360 Threshold'	2	4	6	10	14	20	26	34	191
Trk 14J1- 5.0 % of 3 Average Daily Runway 14 Stage III Departures 2	0	0	0	0	0	0	0	0	0

Arrivals

Altitude (Feet AGL)	3,000	4,000	5,000	6,000	7,000
7210.360 Threshold	65	116	198	305	455
Trk 32A2: 5.0 % of 8 Average Daily Runway 32 Stage III Arrivals	0	0	0	0	0
Trk 32A1: 5.0 % of 22 Average Daily Runway 32 Stage III Arrivals	1	1	1	1	1

Since the estimated number of daily operations on the affected tracks are less than the thresholds, no further analysis is required.

1 Represents the minimum number of daily operations by large airplanes required to increase noise levels by 5 dB DNL or more.

2 Average daily operations source: LAIP INIVI data files

	AW	0	0	0	0	0

Shaded boxes indicate that the threshold has been exceeded and further analysis (Steps 2, 3, and/or 4 of the N7210.360 process) is necessary

5. Step 2, Does this action introduce large jet airplanes over residential areas which are not routinely exposed to noise from large jet airplanes as defined in Table 2 of N7210.360? In both the build an no-build scenarios, departure operations were found to exceed the established thresholds. As a result, Step 2 of the process was applied. This involved comparing the proximity of new tracks to existing tracks at various altitudes (See Table 2). Since all of the new jet tracks were found to be within the "no change lateral minima" of existing tracks, the answer to the above question was no. This finding required application of Step 3.

Table 2: Analysis of New Tracks For Runway 14/32

Application of Step 2, Table 2, FAA N7210.360

Aircraft Altitude (ft. AGL)	No Change Lateral Minima (nm)
3,000 - 6,000	**1**
6,000 - 12,000	**2**
above 12,000	3

6. Step 3, In the case of a proposed action which only changes the aircraft altitudes andlor numbers of daily operations of large jet airplanes on an existing route or track will these changes result in a 5 decibel increase in aircraft noise as defined in Table 3 of N7210.360? Although Step 2 resulted in the finding that no additional residential areas would be subject to overflights by large jets, it is apparent that the introduction of Runway 14/32 would allow an increase in the number of operations on specific existing routes. Currently, jet operations using Runway 33L arrive from the northwest (down wind leg 33L) or from the southeast over water (straight-in approach). All jet departures to the east/southeast (Runways 9 and 15R) are over water. Given unidirectional operation, these are the same routes that would be used by Runway 14/32 operations. Step 3 examines the percentage change in the number of operations on existing routes between the action vs no action cases (build over no-build) to determine if an increase of 5 dB DNL or greater may result. The percentage change values were determined for each corridor and compared to the values given in the FAA notice (see Table 3). Table 3 in the FAA notice associates percentage increases or decreases in operations with a dB level. Nearly half of the percentage changes were decreases in the noise levels of existing corridors when compared to the No Build scenario. Of the increases, only one departure and three arrival corridors were identified. These included departures to the southwest (Corridor DSW, primarily departures from Runway 27), arrivals from northwest (Corridors 33RB and 33RD aircraft from the northwest arriving over water via a right-downwind to 32/33L), and arrivals from the southeast (32/33L arrivals over water). This finding required application of the fourth and final step in the N7210.360 screening process.

Table 3: Comparison of Operations Build vs No-Build by Corridors

Application of Step 3, Table 3 FAA Notice 7210.360 (5.0 % of Stage III Operations by Corridor)

Departures					
Corridor	**No-Build**	**Build**	**Operations Change**	**Altitude Change**	**Change in Noise Exposure**
DE	9	8	-11%	0%	0
DE2	9	8	-11%	0%	0

ASE	1	4	300%	0%	>8
ASW	0	0	0%	0%	0
AW	0	0	0%	0%	0

Shaded areas indicate possibly significant increases in noise levels and require application of Step 4 of the 7210.360 process.

6. Step 4, Taking into account the type of residential community, will the noise from large jet airplanes result in a 5 decibel increase to <u>the overall noise</u> exposures as defined in Table 4 of N7210.360? Since increases in aircraft noise exposure of 5 dB DNL or more were discovered, Step 4 was applied. In addition to the baseline threshold levels provided in the FAA notice additional levels are provided for overflights given various land-use types. In Step 1 of the analysis, only thresholds for the baseline "Quiet Suburb" land use category was considered. The "Quiet Suburb" consists of residential communities where the primary land use is considered to be single family detached dwellings on large lots. Step 4 introduces additional categories including "Normal Suburb" which consists of single family detached dwellings on 1/4 to 1/3 acre lots; "Urban" and "Noisy Urban." No arrival operations exceeded the thresholds for the Quiet Suburb classification and so further analysis was not required. A few departure operations exceeded the Quiet Suburb threshold (see Table 4). Primarily departures to the southwest (the initial departure from runway 27) were involved. Since these tracks are over areas that may be defined as Urban or Noisy Urban, and operations did not exceed the thresholds for Normal Suburb areas, further action was not indicated. This final step concluded the N7210.360 screening process.

Table 4: Analysis of Minimum Number of Daily Large Jet Departure Operations within the Affected Corridor

Application of Step 4, Table 4, FAA Notice 7210.360

Aircraft Altitude (ft. AGL)	Jet Departures using Corridor DSW		Residential Community (see below)			
	Build	No Build	Quiet Suburb	Normal Suburb	Urban	Noisy Urban
3,000	7	1	2	7	22	68
4,000	3	0	4	12	38	119
5,000	3	0	6	20	63	198
6,000	4	0	10	30	95	300
7,000	4	0	14	44	139	438
8,000	4	0	20	62	195	
9,000	4	0	26	83	262	
10,000	4	0	34	109	343	
11,000	4	0	45	142	450	
12,000	4	0	65	205		
13,000	4	0	72	229		
14,000	4	0	89	282		
15,000	4	0	109	343	> 500	
16,000	4	0	130	412		
17,000	4	0	159			
18,000	4	0	191			

Residential Community	Description
Quiet Suburb	Single family detached dwellings on large lots
Normal Suburb	Single family detached dwellings on 1/4 to 1/3 acre lots
Urban	Multi-family dwellings (apartment buildings, row housing, etc.)
Noisy Urban	Multi-family dwellings (high-rise apartments) near busy roads or industrial areas

7. Conclusion

Application of FAA Notice 7210.36 to the Logan Airside Improvements, including unidirectional Runway 14/32, concludes that further noise review is not necessary based on the noise screening procedure for certain air traffic actions above 3,000 feet AGL. The 7210.360 checklist is attached to this memo.

Noise Screening Procedure for Certain Air Traffic Actions Above 3,000 lost AGL

Checklist

Application

The screening procedure applies to new or modified arrival/departure procedures and new or modified airways which meet the following conditions:

(Check appropriate boxes)

- ✈ Involves airports with more than 1,500 large jet airplane (greater than 75,000 lbs.) operations per year, either current or projected whichever is most appropriate..... ☒

and

- ✈ Represents a permanent change or planned test..... ☒

and

- ✈ Concerns changes to departure routes or tracks, used by large jet airplanes, between 3,000 and 18,000 feet AGL/

or

- ✈ Changes to arrival routes or tracks, used by large jet airplanes, between 3,000 and 7,000 feet AGL..... ☒

(If at lease 3 boxes have been checked, proceed to screening procedure.)

Noise Screening Procedure

STEP 1. Does the proposed action introduce noise exposure from large jet airplanes (>75,000 lbs.) which may require further review of the noise impacts as defined in Table 1 (see page 7)?

(Check appropriate boxes)

- ✈ If the estimated number of daily operations on the affected route are greater than the minimum, the answer is YES and proceed to STEP 2 to answer whether the proposed action introduces jet aircraft noise for the first time on a routine basis.

- ✈ If the estimated number of daily operations on the affected route are less than the minimum, the answer is NO and further noise review is NOT necessary. Refer to FAA Order 1050.1D for guidance on the extraordinary factors to consider..... ☐

STEP 2. Does this action introduce large jet airplanes over residential areas which are not routinely exposed to jet aircraft noise as defined in Table 2 (see page 8)?

(Check appropriate boxes)

- ✈ If the location of any existing route or track is at least 3 n. mi. from the new route or track, the answer is YES and proceed to STEP 4 to determine the need for further action..... ☐

- ✈ If the new or moved route or track lies within the No Change lateral minimum of an existing route or track, the answer is NO and proceed to STEP 3 to determine whether the action will cause a 5 decibel increase in existing aircraft noise exposure. ..... ☒

- ✈ If the new or moved route or track lies outside the NO Change lateral minimum of an existing route, the answer is YES and proceed to STEP 4 to determine whether the action represents a 5 decibel increase in the overall noise exposure. ..... ☐

STEP 3. In the case of a proposed action which only changes the aircraft altitudes and/or numbers of daily operations of large jet airplanes on an existing route, will these changes result in a 5 decibel increase in aircraft noise exposure as defined in Table 3 (see page 9)?

(Check appropriate boxes)

- ✈ If the change in aircraft noise exposure is equal to or greater than 5 decibels, the answer is YES and proceed to STEP 4 to determine whether the change in aircraft noise exposure is also a 5 decibel increase in the overall noise exposure. ..... ☒

- ✈ If the change in aircraft noise exposure is less than 5 dB, the answer is NO, and further noise review is NOT necessary. Refer to FAA Order 1050.1D for guidance on the extraordinary factors to consider. ..... ☐

STEP 4. Taking into account the type of residential community, will the noise from large jet airplanes result in a 5 decibel increase in the overall noise exposure as defined in Table 4 (see page 10)?

(Check appropriate boxes)

- ✈ If the estimated number of daily operations on the affected route are greater than the minimum, the answer is YES, consult with the appropriate policy offices and the Regional Assistance Chief Counsel, and refer to FAA Order 1050.1D for guidance or additional procedures to use in considering the environmental consequences ... ☐

- ✈ If the estimated number of daily operations on the affected route are less than the minimum, the answer is NO and further noise review is NOT necessary. Refer to FAA Order 1050.1D for guidance on the extraordinary factors to consider. ..... ☒

Further Environmental Review

STEP 4 was the last step of the noise screening procedure. In reaching this point, the screening procedure has established that the proposed action may cause at least a 5 decibel increase in the overall noise exposure. This information becomes one factor in the determination as to whether the action is likely to be highly controversial and therefore not eligible for a categorical exclusion.

(Check appropriate boxes)

- ✈ Refer to FAA Order 1050.1D for guidance on additional factors to consider and the procedure to follow ..... ☐

- ✈ Consult with the appropriate policy offices and the Regional Assistant Chief Counsel to determine the applicability of the pertinent sections of Order 1050.1D dealing with environmental assessments..... ☐

- ✈ If the screening procedure predicts a 5 decibel increase in the overall noise exposure, out the decision has been made not to do an environmental assessment, prepare supporting Record of Decision ..... ☐

2015 Noise Results

APPENDIX E -- NOISE

Supplemental Results of 2015 High Regional Jet Fleet Analyses

Tables E-1 through E-5 below provide data for each of the study alternatives examined as part of the analysis of the 2015 High Regional Jet Fleet. Except for the Time-Above-Threshold calculations, the tables duplicate the results for the No-Action and Preferred Alternatives (4 and 1A) that were presented in the body of the text but provide the additional information on Alternatives 1 and 2/3 for the first time here. In the case of the Time-Above calculations, results for ALL alternatives are reported here in the Appendix.

School Day Noise Contours for Preferred Alternative 1A -- 29 Million Low Fleet

Also supplementing the analyses included in this document is a depiction of the noise exposure extending over an 8-hour school day. The exposure levels reported here are comparable to the Nighttime Equivalent Sound Levels reported elsewhere in the Noise Sections of this document as Leq(N). In this case, however, the period covered by the metric is an average weekday between 15 September and 15 June, covering the hours from 8:00 a.m. to 4:00 p.m. The metric is referred to as Leq(8). The contours shown in the accompanying Figure E-1 represent the exposure resulting from the operations projected to occur during this 8-hour period under the 29 Million Low Fleet and Preferred Alternative 1A with the new unidirectional Runway 14/32. The 29 Million Low Fleet was selected for this analysis because it represents the greatest degree of impact as measured by numbers of people exposed to DNL values greater than 65 dB.

The figure shows the Leq(8) noise contours at values of 60, 65, and 70 dB of exposure overlaid on a basemap showing local schools in the vicinity of Logan Airport. An Leq(8) of 60 dB represents the probable lower limit of any area where school sound insulation of an untreated building is likely to benefit. Though there is no firm standard which guides the sound insulation of classrooms, a normal goal for such programs is to design for at least 5 decibels of reduction and achieve an interior 8-hour equivalent sound level of no more than 45 decibels. With an outdoor Leq(8) of 60 dB (which would exist for any school located on the 60 dB contour in Figure E-1), achievement of an interior level of 45 dB requires only 15 decibels of noise reduction. That degree of reduction occurs in normal school construction, even with windows open.

Given that no schools fall within the 60 dB Leq(8) contour for the Preferred Alternative under the 29 Million Low Fleet, it is expected that no sound insulation of schools will be necessary.

Figure E-1 – 8-Hour Equivalent Sound Levels During an Average School Day for the 29M Low Fleet and Preferred Alternative 1A

Comparison of Noise Results for all Alternatives
Excerpted from the Draft EIS/EIR

Excerpt from the Airside Draft EIS/EIR Noise Results

Table 6.2-1
1999 and 2010 Logan Average Daily Operations—Without Peak Period Pricing (Alternatives 1A and 4)

	Stage 2 Aircraft		Stage 3 Aircraft		Turboprop Aircraft		Totals	
Fleet Forecast	Day	Night	Day	Night	Day	Night	Day	Night
1999 - 29M Low	16	5	715	90	562	10	1292	105
1999 - 29M High[1]	20	2	724	60	653	54	1396	115
2010 - 37.5M Low	0	0	814	102	562	11	1376	113
2010 - 37.5 High	0	0	877	118	658	13	1534	130
2010 - 45M High	0	0	954	126	707	13	1660	139

Note: "Day" defined as 7:00 AM to 9:59 PM and "Night" defined as 10:00 PM to 6:59 AM.
(1) The 1999 29M High Fleet forecast reflects a greater proportion of turboprop aircraft in both day and night than do the other four fleets.

Table 6.2-2
1999 and 2010 Logan Average Daily Operations—With Peak Period Pricing (Alternatives 1, 2 and 3)

	Stage 2 Aircraft		Stage 3 Aircraft		Turboprop Aircraft		Totals	
Fleet Forecast	Day	Night	Day	Night	Day	Night	Day	Night
1999 - 29M Low	16	5	715	90	551	10	1282	105
1999 - 29M High	20	2	724	60	591	54	1334	115
2010 - 37.5M Low	0	0	814	102	543	11	1358	113
2010 - 37.5M High	0	0	877	118	504	13	1580	130
2010 - 45M High	0	0	954	125	536	13	1490	138

Note: "Day" defined as 7:00 AM to 9:59 PM and "Night" defined as 10:00 PM to 6:59 AM.

Table 6.2-5
Achievement of Annual PRAS Runway Use Goals

	Variance from Annual PRAS Goals by Fleet[1]			
	1993	1999 - 29M	2010 - 37.5M	
Improvement Concept	Base	Low	Low	High
Perfect PRAS Compliance	0.0	0.0	0.0	0.0
Alternative 1 - All Actions	N/A	33.2	73.5	64.8
Alternative 1A - All Except Peak Period Pricing	N/A	33.4	74.8	63.6
Alternatives 2 and 3 - All Except Runway 14/32 and No Build	N/A	68.1	107.8	140.5
Alternative 4 - No Action	73.3	73.4	115.5	147.5

(1) Variance from PRAS Goals is measured as the sum of absolute deviations from PRAS Goals. An improvement in PRAS compliance is measured as a decline in the sum of absolute percentage deviations. Zero represents perfect PRAS compliance.

Table 6.2-6
Population Summary

Day-Night Sound Level in dB	1993	All Actions Alternative 1	All Except Peak Period Pricing Alternative 1A	All Except Runway 14/32 and No Build Alternatives 2 and 3	No Action Alternative 4
1999 - 29M Low Fleet					
Greater or equal to 75 dB	568	77	77	222	257
Greater or equal to 70 dB	6,380	1,382	1,459	1,445	1,521
Greater or equal to 65 dB	34,386	17,677	17,909	16,892	17,531
2010 - 37.5M Low Fleet					
Greater or equal to 75 dB	568	0	58	58	135
Greater or equal to 70 dB	6,380	670	730	1,676	2,208
Greater or equal to 65 dB	34,386	10,481	10,481	10,239	10,450
2010 - 37.5M High Fleet					
Greater or equal to 75 dB	568	58	58	257	257
Greater or equal to 70 dB	6,380	1,213	1,028	3,321	3,828
Greater or equal to 65 dB	34,386	13,351	12,007	11,548	11,499

1. Estimated cumulative numbers of people living in areas where the noise from aircraft flight operations equals or exceeds the indicated value of the annual average Day-Night Sound Level.
2. All estimates are based on runway use chosen to most nearly meet PRAS goals and reflect the effects of delayed aircraft as determined by the DELAYSIM model.

Table 6.2-7
Comparison of the Noise-exposed Population for Alternatives 1, 1a, 2 and 3 to the No Action Alternative

	Percent Difference Compared to No Action (Alternative 4)		
Day-Night Sound Level in dB	**Alternative 1**	**Alternative 1A**	**Alternatives 2 and 3**
1999 - 29M Low Fleet			
Greater or equal to 75 dB	-70%	-70%	-14%

Noise Metrics

A variety of noise metrics are used to assess airport noise impacts in different ways. Noise metrics may be used to describe individual noise events (such as a single operation of an aircraft taking off overhead) or groups of events (such as the cumulative effect of numerous aircraft operations, the collection of which creates a general noise environment, or overall noise exposure level). Both types of metrics are helpful in explaining how people are affected by a given noise condition. Massport uses both single-event and cumulative noise metrics to gain a full understanding of the Logan noise environment.

A-Weighted Sound Level.

The basic descriptor of the magnitude of sound is the value of its sound pressure. Sound pressure is a physical quantity which varies constantly in magnitude and in frequency. Because the range of the values of sound pressure is very large, acousticians adopted a logarithmic ratio scale to describe its magnitude. The unit on this logarithmic scale is the deciBel (dB). To match the unequal sensitivity of the human ear to different frequencies, standard filters have been developed for noise measuring equipment, causing the instruments to respond to sound pressures similar to the way in which we hear. The most common filter is the "A" weighting; it significantly de-emphasizes low frequencies (less than 500 Hertz (Hz)) and very high frequencies (above 10,000 Hz); and it relates well to our ability to hear speech. Sounds measured through this filter are referred to as A-weighted sound levels. The A-weighted dB is the most common sound unit used to evaluate all forms of noise impact on people.

Equivalent Sound Level.

Equivalent sound level (Leq) is the A-weighted sound level of a steady-state noise during a specified period of time containing the same amount of sound exposure as the varying sound level within that period of time. Leq is a metric for describing noise with fluctuating levels. As Leq is related to sound exposure rather than just sound pressure, averaging emphasizes the higher sound levels, and thus affords a good measure of high level intrusive noises. Also, because the sound exposure accounts for both sound level and duration, the Leq provides a good measure of long duration noise events. In this study the Leq is used to describe the nighttime sound level which is the summation of the sound exposure from all of the individual events that occur between the hours of 10:00 PM and 7:00 AM. Unlike DNL which includes both day and night sound levels, the nighttime Leq (LeqN) focuses only on the nighttime period, and does not include the 10 dB penalty surcharged on DNL levels.

Day-Night Sound Level (DNL).

The DNL is the A-weighted sound level of a steady-state noise during a 24-hour day which contains the same sound exposure as does the summation of the sound exposures from all of the individual events that occur during a 24-hour period, with the provision that noises occurring at night (defined as 10:00 PM through 7:00 AM) are increased by 10 dB. Actually, it is a 24-hour Leq, but adjusted with a nighttime penalty. This 10 dB penalty, or weighting, reflects the added intrusiveness of nighttime noise. Since community background noise typically decreases about 10 dB at night, nighttime noise events sound relatively louder because there is less ambient noise. Because DNL is based on an accumulation of total sound exposure, every noise event, regardless of level or duration, adds to its value.

Environmental sound levels can be measured or estimated. Measurements are practical only for obtaining existing DNL values for a relatively limited number of geographic locations and, in the absence of permanently installed monitors, only for a period of a few days. For this reason, most airport noise assessments use computer-generated DNL estimates of the noise contours for both existing and future conditions. Computation of DNL is accomplished by adding together the sound exposure level values of each individual aircraft flight that adds to the noise exposure at each location in the study area. In most airport studies, as in this study, the operations used in computing DNL represent an average day during a given year as determined by the statistical data maintained by Massport, the FAA, and other sources. The results are presented on maps as contours of equal cumulative sound (e.g., DNL values of 60, 65, 70 and 75 dB) and in tables for both DNL and other metrics at specific locations. They are generated by a program developed by the FAA known as the INM.

Maximum Sound Level.

The maximum sound level metric, Lmax, represents the highest sound level during a single noise event. During an aircraft flyby the sound level at a receptor increases during its approach from the time that it is first audible to its maximum level when the aircraft is nearest, or just past, the receptor. Then, as the aircraft flies away the sound level decreases until it is no longer audible. The total sound exposure during such a flyby is related to the sound pressure at the time the maximum sound level (Lmax) and to the duration of the time that the aircraft sound was audible.

Time Above a Given Noise Threshold.

Because analyses of sound levels (of any variety) are complex and often unfamiliar to the public, the FAA has developed a supplemental metric which describes the statistical distribution for the varying sound levels which together comprise the total noise environment. This descriptor accumulates the time that the sound level exceeds a selected A-weighted sound level threshold value. Every moment that the fluctuating sound level rises above the threshold, the number of seconds is accumulated and added to those acquired during previous periods. In this study these time-above-thresholds, or Time Above (TA), are reported in minutes for an average 24-hour period or just for nighttime periods between 10:00 PM and 7:00 AM. To provide a statistical picture of the noise environment the TA must be computed for several threshold values.

Appendix F
Air Quality

- F.1 Comparison of Air Quality Modeling Results for the 29M Low Scenario, Alternative 1/1A LDMS vs. EDMS Modeling
- F.2 Aircraft Fleet Used for EDMS Modeling
- F.3 2015 RJ Fleet – Emission Inventory Result
- F.4 2015 RJ Fleet – Dispersion Modeling Results
- F.5 Comparison of Air Quality Results for All Alternatives Excerpted from the Draft EIR/EIS

Comparison of Air Quality Modeling Results

Comparison of Air Quality Modeling Results for the 29M Low Scenario, Alternative 1/1 A

	2nd Maximum CO (1-hour)			2nd Maximum N02 (1-hour)			2nd Maximum CO (8-hour)			2nd Maximum PM-10 (24-hour)			AnnualMean $N0_2$			AnnualMean PM-10		
Receptor	LDMS	EDMS	Std.	LDMS	EDMS	Std.	LDMS	EDMS	Std.	LDMS	EDMS	Std.	LDMS	EDMS	Std.	LDMS	EDMS	Std.

Union Park	4,024	3,706	40,000	188	177	320	2,176	2,132	10,000	45	45	150	53	53	100	23	23	50

All values are given in $\mu g/m^3$.

LDMS is the Logan Dispersion Modeling System.

EDIVIS is the FAA Emissions and Dispersion Modeling System.

Std. is the National Ambient Air Quality Standard (NAAQS) for the specified pollutant, except in the case of NO_2, which has no NAAQS for the one-hour averaging time.

For NO_2, the standard is a state policy level standard.

2015 RJ Fleet –Dispersion Modeling Results

AIR QUALITY DISPERSION MODEL RESULTS FOR LOGAN AIRPORT
CO, SECOND HIGHEST ONE-HOUR LEVELS
NO ACTION ALTERNATIVE
2015 HIGH RJ FLEET

RECEPTOR LOCATION	CONCENTRATION ($\mu g/m^3$)
1. East Boston (Jeffries Point)	6,125
2. East Boston (Constitution Beach)	4,294
3. East Boston (Bayswater)	4,245
4. Winthrop (Court/Loring St.)	4,174
5. Winthrop (Cottage Park)	3,884
6. Winthrop (Grandview)	3,801
7. Castle Island	4,260
8. C & Broadway	3,856
9. South End (Union Park)	4,067
10. Eagle Hill	4,594
11. Orient Heights	4,069
12. Revere Beach	3,886

All concentrations include a background level of 3,420 $\mu g/m^3$

Ambient air quality standard = 40,000 $\mu g/m^3$

AIR QUALITY DISPERSION MODEL RESULTS FOR LOGAN AIRPORT
CO, SECOND HIGHEST EIGHT-HOUR LEVELS
NO ACTION ALTERNATIVE
2015 HIGH RJ FLEET

RECEPTOR LOCATION	CONCENTRATION ($\mu g/m^3$)
1. East Boston (Jeffries Point)	2,922
2. East Boston (Constitution Beach)	2,307
3. East Boston (Bayswater)	2,308
4. Winthrop (Court/Loring St.)	2,300
5. Winthrop (Cottage Park)	2,133
6. Winthrop (Grandview)	2,161
7. Castle Island	2,236
8. C & Broadway	2,121
9. South End (Union Park)	2,186
10. Eagle Hill	2,319
11. Orient Heights	2,219
12. Revere Beach	2,148

All concentrations include a background level of 2,052 $\mu g/m^3$

Ambient air quality standard = 10,000 $\mu g/m^3$

AIR QUALITY DISPERSION MODEL RESULTS FOR LOGAN AIRPORT
NO_2, SECOND HIGHEST ONE-HOUR LEVELS
NO ACTION ALTERNATIVE

➤ G.1 Letter from U.S. Fish and Wildlife Service dated April 1, 1997

United States Department of the Interior

FISH AND WILDLIFE SERVICE
New England Field Office
22 Bridge Street, Unit #1
Concord, New Hampshire 03301-4996

April 1, 1997

Jennifer O'Reilly
Jason M. Cortell and Assoc. Inc.
244 Second Avenue
Waltham, MA 02154

Dear Ms. O'Reilly:

This responds to your letter dated March 17, 1997 for information on the presence of federally-listed and proposed, endangered or threatened species in accordance with preparation of an environmental impact statement/environmental impact report for improvements to airfield operations at Logan International Airport in Boston, Massachusetts.

Based on information currently available to us, the only federally-listed or proposed, threatened and endangered species under the jurisdiction of the U.S. Fish and Wildlife Service known to occur in the project area is the endangered peregrine falcon (*Falco peregrinus*). A pair of peregrine falcons nest in downtown Boston. Falcons are predators and the Boston peregrines are known to search for prey over the clear zones and other open spaces in and around Logan Airport. However, we do not anticipate that the peregrine falcons in Boston will be adversely affected by the proposed airfield improvements.

Preparation of a Biological Assessment or further consultation with us under Section 7 of the Endangered Species Act is not required. Should project plans change, or additional information on listed or proposed species becomes available, this determination may be reconsidered.

A list of federally-designated endangered and threatened species in Massachusetts is enclosed for your information. Thank you for your cooperation and please contact Michael Amaral of this office at 603-225-1411 if we can be of further assistance regarding endangered species.

Sincerely yours,

Michael J. Bartlett
Supervisor
New England Field Office

Enclosure

FEDERALLY LISTED ENDANGERED AND THREATENED SPECIES IN MASSACHUSETTS

Common Name	Scientific Name	Status	Distribution
FISHES:			
Sturgeon, shortnose*	Acipenser brevirostrum	E	Atlantic coastal waters and rivers (Conn. R.)
REPTILES:			
Turtle, bog	Clemmys muhlenbergii	PT	Berkshire County
Turtle, green*	Chelonia mydas	T	Oceanic staggler in southern New England
Turtle, hawksbill*	Eretmochelys imbricata	E	Oceanic straggler in southern New England
Turtle, leatherback*	Dermochelys coriacea	E	Oceanic summer resident
Turtle, loggerhead*	Caretta caretta	T	Oceanic summer resident
Turtle, Atlantic ridley*	Lepidochelys kempii	E	Oceanic summer resident
Turtle, Plymouth redbelly	Chrysemys rubriventris bangsi	E	Plymouth & Dukes Counties
BIRDS:			
Eagle, bald	Haliaeetus leucocephalus	T	Nesting in Quabbin Res. and along Conn. R.; entire state-migratory
Falcon, American peregrine	Falco peregrinus anatum	E	Current nesting: Boston & Springfield; entire state-migratory
Falcon, Arctic peregrine	Falco peregrinus tundrius	T	Entire state-migratory
Plover, Piping	Charadrius melodus	T	Atlantic coast
Roseate Tern	Sterna dougallii dougallii	E	Atlantic coast
MAMMALS:			
Whale, blue*	Balaenoptera nyusculus	E	Oceanic
Whale, finback*	Balaenoptera physalus	E	Oceanic
Whale, humpback*	Megaptera novaeangliae	E	Oceanic

Re: Logan Airside Improvements Planning Project, EOEA #10458
Boston-Logan International Airport, Boston, MA

Dear Ms. McDonough:

The Federal Aviation Administration (FAA) and the Massachusetts Port Authority (Massport) are undertaking a study of alternatives for reducing current and projected levels of aircraft delay at Boston-Logan International Airport. The FAA is the lead federal agency for purposes of airport layout plan approval and funding approval. The FAA is also the project proponent with respect to the reduction in runway approach minimums and implementation of runway instrumentation. Massport is the project proponent for all other improvement concepts that fall within its purview as proprietor of Logan.

The FAA and Massport prepared a draft Environmental Impact Statement/Draft Environmental Impact Report (Draft EIS/EIR) for the Logan Airside Improvement Planning Project (Airside Project). A copy of the document was forwarded to the Massachusetts Historical Commission (MHC) in February 1999. The Draft EIS/EIR reflects the analytic process for identifying and reviewing the operational and environmental implications of various improvement alternatives and designates a preferred alternative for implementation. The preferred alternative includes the construction of a runway to serve commuter planes, known as Runway 14/32. The runway will be designed and approved for unidirectional use only, with all arrivals and departures taking place over Boston Harbor.

The purpose of this letter is to coordinate consultation among the FAA, Massport, and the MHC in compliance with Section 106 of the National Historic Preservation Act, as amended (36 CFR 800), Section 4(f) of the Department of Transportation Act of 1966, and Massachusetts General Laws Chapter 9, Sections 26-27C, as amended by Chapter 254 of the Acts of 1988 (950 CMR 71). The FAA has determined under Section 106 that the Airside Project would constitute an undertaking and that it is a type of activity that has the potential to cause effects on historic properties (36 CFR 800.3).

The Draft EIS/EIR includes an assessment of impacts of the preferred alternative on historic properties. As summarized in Section 8.6 of the Draft EIS/EIR, the proposed runway would have no direct impacts to significant historic properties; however, sound insulation mitigation could have

the potential for indirect impacts. The analysis of potential impacts was performed by comparing the 65-decibel (dB) day-night average sound level (DNL) noise contours of the No Action Alternative (Alternative 4) and the Preferred Alternative (Alternative 1A). Project impact areas for historic properties are those areas where the 65-dB DNL contour for the preferred alternative extends beyond the 65-dB DNL contour for the no action alternative. Overall, the preferred alternative reduces the population exposed to the most severe noise impacts (greater than 70dB) when compared with the no action alternative. Where the 65-dB DNL contour increases with the preferred alternative, the increase is less than 1.5-dB, a threshold of significance in Part 150.

A review of MHC and local historical commission files and field survey conducted to confirm background research resulted in the identification of historic properties in Boston, Chelsea, and Winthrop that are within the 65-dB DNL. The historic properties are enumerated below and depicted on the enclosed figures.

Boston

St. Andrews Road MHC #EB1017, East Boston
Boston Army Supply Base, MHC #RT, South Boston (NR eligible 1997)
C Street Area, MHC #RU, South Boston (NR eligible 1997)

Chelsea

A section of the Bellingham Square Historic District (NR listed 1985)
A section of the Downtown Chelsea Residential District (NR listed 1988)

Winthrop

45 Enfield Road, MHC #67
240 Pleasant Street MHC #158 (NR eligible 1997)
75 & 77 Somerset Avenue MHC #196
88 Somerset Avenue MHC #197
94 Somerset Avenue MHC #198 (NR eligible 1997)

We evaluated airport noise and land use compatibility in accordance with land use guidelines expressed in Federal Aviation Regulation (FAR), Part 150, Airport Noise Compatibility Planning (14 CFR 150). FAR Part 150 does not include guidelines specific to historic sites; however, the identified historic properties are comprised of commercial, manufacturing, and residential land uses, for which guidance is provided. In addition, general guidance within FAR Part 150 indicates that noise levels generally do not affect the relevant characteristics of urban historic districts (for example, their architectural features and recognition of their place in history). FAR Part 150 provides that all land uses are considered to be compatible with noise levels less than 65-dB DNL and that commercial and manufacturing land uses are compatible land uses within the 65-dB to 70-dB DNL. FAR Part 150 further provides that residential land uses are not compatible within the 65-dB DNL, but does allow for noise impacts to be mitigated through sound insulation of affected residential structures.

The FAA and Massport propose to mitigate noise impacts by sound insulating all affected residences, historic and non-historic, that fall within the 65-dB DNL contour for the Preferred Alternative. The structures to be included within the noise mitigation program would be subject to a detailed block-by-block analysis during project implementation. All sound insulation of historic structures would be undertaken in compliance with applicable federal and state guidelines to ensure protection of the resources. Preservation measures to maintain the existing form, integrity, and materials of the historic properties would be accomplished in accordance with the Secretary of the Interior's Standards for the Treatment of Historic Properties (36 CFR 68). The FAA and Massport would consult with the MHC as it has done previously with sound insulation of historic structures impacted by other Logan projects (i.e., South Boston).

Based on the level of planning to date, the FAA has determined that the sound insulation mitigation proposed under the Preferred Alternative has the potential to cause effects on historic properties (36 CFR 800.3). Given FAA and Massports' intent to specify as a mitigation measure that sound insulation will be implemented in accordance with the Secretary of the Interior's Standards for the Treatment of Historic Properties (36 CFR 68), we propose a Determination of No Adverse Effect (36 CFR 800.5 (b)) on significant historic properties.

The FAA and Massport welcome the opportunity to review in more detail the proposed undertaking, identification of historic properties, and proposed determination of effect with the MHC. Please do not hesitate to contact Maureen Cavanaugh of Frederic R. Harris, Inc. (617-371-4489) or me if you have any questions or require additional information. Thank you in advance for your careful consideration of the Logan Airside Project.

Sincerely,

John C. Silva

Paving Emissions	0	26,174.21	0	0	0
Fugitive Dust Emissions[1]	0	0	0	0	19,282.70
Total	**(lbstyr):**	**39,968.43**	**145,044.73**	**68,684.53**	**25,196.26**
	(tonslyr): [2]	**19.98**	**72.52**	**34.34**	**12.60**
	(kg/day):	**49.67**	**180.25**	**85.36**	**31.31**

[1] This total represents fugitive dust emissions with no control measures. Control measures such as application of water and use of silt fences will reduce this total substantially.

[2] The *de minimis* values are 50 tons per year (tpy) for VOCs and NOx and 100 tpy for CO.

Annual Construction-related Air Emissions – 2003

Construction Equipment	Usage (hrs)	Emissions (lbs) VOCs	CO	NOx	PM
